The Australian Needle and Syringe Program Survey is funded by the Australian Government Department of Health. The Kirby Institute is affiliated with the Faculty of Medicine, UNSW Sydney.

ACKNOWLEDGEMENTS

We would like to acknowledge the many people who assist each year in the development and conduct of the Australian NSP Survey (ANSPS), particularly the clients, staff and managers at participating NSP services. We also appreciate the dedication and vision of the founding members of the project and the late Dr Margaret MacDonald who was responsible for the development and conduct of the ANSPS from 1995 until 2003.

Special thanks go to Mr Philip Cunningham, Senior Scientist and Operations Manager, Ms Beth Catlett, DBS Coordinator and Mr Mitchell Starr, Senior Hospital Scientist at the NSW State Reference Laboratory for HIV at St Vincent's Hospital and St Vincent's Centre for Applied Medical Research. We also appreciate the assistance provided by Ms Rachel McCleave from the Kirby Institute and Mr Greg Smith and Mr Ashwin Prekesh from Educational Assessment Australia, UNSW Global Pty Limited.

In 2018, the project received support and input from the following members of the ANSPS National Advisory Group: Ms Jennifer Taleski (ACT); Ms Annabelle Stevens (NSW); Mr David Decolongon (NT); Mr Stephen Lymb and Mr Rob Gerrie (SA); Ms Francine Smith and Ms Myf Briggs (TAS); Mr Brian McDowell and Ms Terrie Spall (VIC); Ms Jude Bevan (WA); Ms Melanie Walker (Australian Injecting and Illicit Drug Users League); and Ms Sue Heard, Dr Jenny Iversen and Professor Lisa Maher (Kirby Institute). We would particularly like to thank Mr Robert Kemp (QLD) for chairing the National Advisory Group.

Ethical approvals were obtained from institutional ethics committees associated with the investigators and participating NSP sites. The Australian Needle Syringe Program Survey is funded by the Australian Government Department of Health and Ageing. The Kirby Institute is affiliated with the Faculty of Medicine, UNSW Sydney.

ABBREVIATIONS

ANSPS	Australian Needle and Syringe Program Survey
DAA	Direct acting antiviral
DBS	Dried blood spot
HCV	Hepatitis C virus
HIV	Human immunodeficiency virus
NSP	Needle syringe program
OST	Opioid substitution therapy
PIEDs	Performance and image-enhancing drugs
PBS	Pharmaceutical Benefits Scheme
RNA	Ribonucleic acid
RSS	Receptive syringe sharing

KEY POINTS

- The Australian NSP Survey (ANSPS) functions as a strategic early-warning system designed to monitor blood borne viral infections and injecting and sexual behaviour among people who inject drugs.
- In 2018, 53 Needle and Syringe Programs (NSPs) throughout Australia participated in the ANSPS and 2,742 NSP attendees completed the survey. The response rate was 45%.

Demographic characteristics:

- Over the five-year period 2014 to 2018, the median age of survey respondents increased from 39 to 42 years, with a concurrent decline in the proportion of young injectors (aged <25 years) from 6% in 2014 to 4% in 2018 (χ^2 trend $p=0.013$).
- The median time since first injection increased from 19 years in 2014 to 22 years in 2018, and the proportion of new initiates (those injecting for less than three years) declined from 7% in 2014 to 5% in 2018 (χ^2 trend $p=0.004$).
- The proportion of respondents from an Indigenous Australian background increased significantly, from 14% to 19% over the period 2014 to 2018 (χ^2 trend $p<0.001$).
- The proportion of respondents reporting incarceration in the 12 months prior to survey completion increased from 11% to 13% over the five-year period 2014 to 2018 (χ^2 trend $p=0.009$).

Injecting behaviour:

- Daily or more frequent injecting in the month prior to the survey was reported by approximately half of respondents in all survey years 2014 to 2018.
- The proportion of respondents reporting methamphetamine as the last drug injected increased from 33% in 2014 to 48% in 2018 (χ^2 trend $p<0.001$). In all years since 2014 methamphetamine was the most commonly reported drug last injected nationally.
- The proportion of respondents reporting heroin as the last drug injected declined from 31% in 2014 to 26% in 2018 (χ^2 trend $p=0.005$).
- Pharmaceutical opioids were the third most commonly reported class of drugs last injected in all years 2014 to 2018, however prevalence declined from 11% to 7% over this period (χ^2 trend $p<0.001$).
- The proportion of respondents who reported last injecting performance and image enhancing drugs (PIEDs) declined from 7% in 2014 to 4% in 2018 (χ^2 trend $p<0.001$).
- In 2014, two in five (42%) new initiates to injection reported last injecting PIEDs and one in three (29%) reported last injecting methamphetamine. Conversely in 2018, two thirds (63%) of new initiates reported last injecting methamphetamine and one in five (18%) reported last injecting PIEDs.
- The proportion of respondents reporting recent reuse of needles and syringes (including reuse of one's own syringes) increased, from 21% in 2014 to 26% in 2018 (χ^2 trend $p=0.023$).
- There was also a significant increase in the proportion of respondents reporting receptive sharing of needles and syringes in the last month, from 16% in 2014 to 18% in 2018 (χ^2 trend $p=0.034$).
- The prevalence of recent receptive sharing of drug preparation equipment remained stable, ranging from 27% to 29% over the five-year period (χ^2 trend $p=0.157$).

- The proportion of respondents who reported injecting in public in the last month increased from 36% in 2014 to 46% in 2018 (χ^2 trend $p<0.001$).
- The prevalence of self-reported drug overdose in the past 12 months increased significantly, from 15% in 2014 to 19% in 2018 (χ^2 trend $p<0.001$).

HIV antibody prevalence:

- HIV antibody prevalence remained low and stable nationally, ranging from 1.4% to 2.1% over the period 2014 to 2018 (χ^2 trend $p=0.641$).
- In all years 2014 to 2018, HIV antibody prevalence was higher among homosexual men compared to bisexual or heterosexual men, and compared to women.
- In 2018, HIV antibody prevalence was higher among Aboriginal and Torres Strait Islander respondents compared to non-Indigenous respondents (3.6% vs 1.1%, $p<0.001$). However, prevalence of HIV infection among Aboriginal and Torres Strait Islander respondents was stable between 2014 to 2018 (range 2.0% in 2014 to 3.6% in 2018, χ^2 trend $p=0.093$).

HCV antibody prevalence:

- Hepatitis C virus (HCV) antibody prevalence declined nationally from 54% in 2014 to 45% in 2018 (χ^2 trend $p<0.001$). This is the second consecutive year that less than half of respondents had been exposed to HCV, following two decades of HCV antibody prevalence $\geq 50\%$ (all years 1999-2016).
- Across all survey years 2014 to 2018, prevalence of HCV antibody was higher among older than among younger respondents and among those with longer injection histories.

HCV treatment uptake:

- Among respondents assessed as eligible for HCV treatment, the proportion who reported a lifetime history of HCV treatment increased significantly, from 13% in 2014 to 55% in 2018 (χ^2 trend $p<0.001$).
- Similarly, among respondents assessed as eligible, the proportion who reported recent (last 12 months) HCV treatment increased significantly, from 1% in 2014 to 39% in 2018 (χ^2 trend $p<0.001$).

HCV RNA prevalence:

- In 2015, the ANSPS commenced HCV ribonucleic acid (RNA) testing in addition to HCV antibody testing. National data from 2017 and 2018 are presented for the first time in this report, along with previously reported data from 2015 and 2016. Jurisdictional data from 2015 to 2018 are also presented for the first time in this report.
- Among respondents tested for HCV RNA, the proportion with detectable HCV RNA declined from 51% in 2015 to 20% in 2018 (χ^2 trend $p<0.001$).
- The proportion of HCV antibody positive respondents with detectable HCV RNA also declined from 76% in 2015 to 42% in 2018 (χ^2 trend $p<0.001$).

INTRODUCTION

The Australian Needle and Syringe Program Survey (ANSPS) provides serial point prevalence estimates of human immunodeficiency virus (HIV) and hepatitis C virus (HCV) antibody prevalence and sexual and injecting risk behaviour among people who inject drugs (PWID) in Australia. Conducted annually over a one-two week period in October, all clients attending participating Needle and Syringe Program (NSP) services are invited to complete a brief, anonymous questionnaire and to provide a capillary blood sample for HIV and HCV antibody testing (see methodological notes [Appendix B] for further details on the ANSPS design and implementation). Commencing in 2015, HCV ribonucleic acid (RNA) testing has been conducted among HCV antibody positive respondents with sufficient dried blood spot (DBS) samples. This report presents national and state/territory findings for the period 2014 to 2018 and HCV RNA data for the period 2015 to 2018.

In 2018, 53 NSP services participated in the ANSPS. Over the period 2014 to 2018, the number of ANSPS respondents ranged from 2,210 to 2,742 and the annual response rate ranged from 41% to 48% (Table 1.1.1). Of the 2,742 ANSPS respondents in 2018, the majority (83%) were recruited from the 43 NSP services that participated in the ANSPS in all years 2014 to 2018. A list of participating NSP services in 2018 is provided at Appendix A.

Demographic Characteristics

Approximately two thirds of survey respondents were male and less than one percent identified as transgender across all survey years 2014 to 2018. In 2018, the majority (78%) of respondents identified as heterosexual, while 9% identified as bisexual and 4% as homosexual (Table 1.1.1).

The proportion of respondents from an Indigenous Australian background increased significantly, from 14% to 19% over the period 2014 to 2018 (χ^2 trend $p < 0.001$)^{1,2}. In all survey years, the majority of respondents were born in Australia (ranging from 85% to 87%), with the United Kingdom, Ireland (4%) and New Zealand (3%) the predominant countries of birth outside Australia in 2018. Most respondents also reported that their parents spoke English at home (range 92% to 94% over the period 2014 to 2018).

The median age at survey completion increased from 39 years in 2014 to 42 years in 2018 and there was a concurrent significant decline in the proportion of young injectors (aged <25 years) from 6% in 2014 to 4% in 2018 (χ^2 trend $p = 0.013$). The median time since first injection increased from 19 years in 2014 to 22 years in 2018, and the proportion of new initiates (those injecting for less than 3 years) declined from 7% in 2014 to 5% in 2018 (χ^2 trend $p = 0.004$). The median age at first drug injection was stable across the period 2014 to 2018, ranging from 18 to 19 years of age (Table 1.1.1).

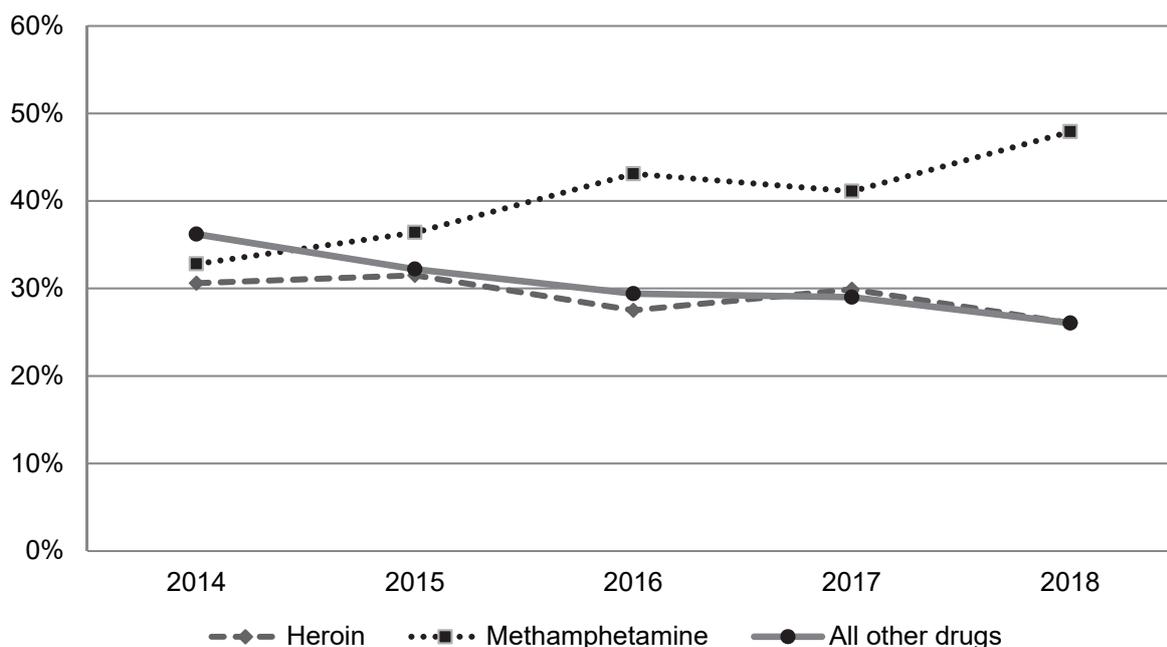

The proportion of respondents reporting incarceration in the 12 months prior to survey completion increased from 11% to 13% over the five-year period 2014 to 2018 (χ^2 trend $p = 0.009$). Approximately one in three respondents (34%) with a history of recent incarceration reported injecting while in prison (Table 1.1.1).

Injecting behaviour

Methamphetamine was the most commonly reported drug last injected nationally in all years 2014 to 2018 (Table 1.1.2). Reports of methamphetamine injection increased significantly over the five-year period, from 33% in 2014 to 48% in 2018 (χ^2 trend $p < 0.001$, Figure 1). In 2018, methamphetamine was the most commonly injected drug in all but one jurisdiction, including the Australian Capital Territory (47%), New South Wales (35%), Northern Territory (40%), Queensland (48%), South Australia (57%), Tasmania (35%) and Western Australia (69%).

Heroin was the second most commonly reported drug last injected nationally in 2018, with a significant decline in prevalence between 2014 (31%) and 2018 (26%, χ^2 trend $p = 0.005$). As in all previous years since 2014, heroin remained the most commonly reported drug last injected in Victoria (51%) in 2018. Heroin was the second most commonly reported drug last injected in the Australian Capital Territory (40%), NSW (30%), South Australia (31%) and Western Australia (15%) in 2018.

Figure 1. Proportion of respondents (%) reporting last injecting heroin, methamphetamine, and all other drugs, 2014–2018

The third most commonly reported class of drugs last injected nationally was pharmaceutical opioids (including morphine, oxycodone and fentanyl), although prevalence declined from 11% to 7% over the period 2014 to 2018 (χ^2 trend $p < 0.001$, Figure 2). In 2018, pharmaceutical opioids were the second most commonly reported class of drugs last injected in the Northern Territory (36%), Queensland (16%) and Tasmania (31%)^{3,4}.

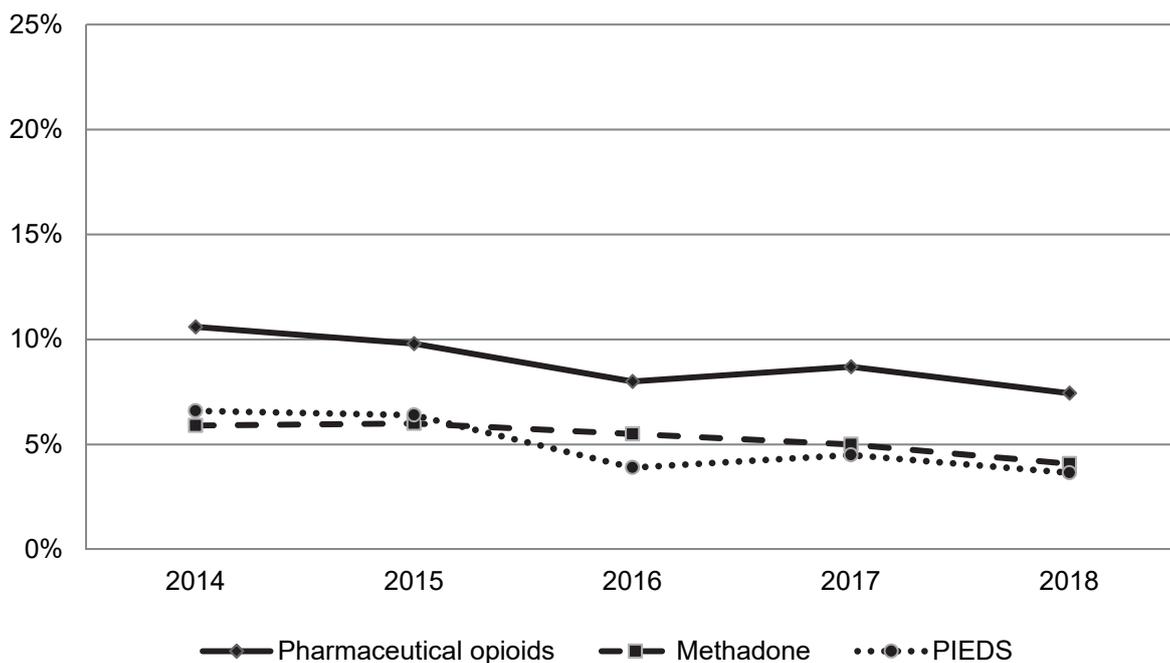

Methadone was reported as the last drug injected by less than ten percent of ANSPS respondents in all years 2014 to 2018 (range 6% to 4%) with a significant decline in prevalence over this period (χ^2 trend $p = 0.002$). In 2018, methadone was the third most commonly reported class of drugs last injected in South Australia (5%) and Tasmania (19%). Buprenorphine and buprenorphine-naloxone

injection were reported by a minority of survey respondents. The prevalence of both buprenorphine-naloxone injection (2% to 1%, χ^2 trend $p=0.551$), and the prevalence of buprenorphine injection (3% to 2%, χ^2 trend $p=0.385$) was stable over the period 2014 to 2018.

A minority of survey respondents (1% across all survey years) reported cocaine as the last drug injected. The prevalence of performance and image enhancing drugs (PIEDs) as the last drug injected declined significantly over the period 2014 to 2018 (χ^2 trend $p<0.001$, Figure 2). PIEDs injection declined from 14% in 2014 to 4% in 2018 in Queensland ($p<0.001$), while prevalence remained stable at between 10% and 12% in NSW (χ^2 trend $p=0.961$). The proportion of respondents who reported last injecting PIEDs was <3% in all other jurisdictions in 2018.

In 2014, PIEDs were the most commonly reported last drug injected among new initiates (less than 3 years since first injection) nationally. However, in each year from 2015-2018, methamphetamine was the most commonly reported last drug injected among this group, with a significant increase observed between 2014 (29%) and 2018 (63%, χ^2 trend $p<0.001$).

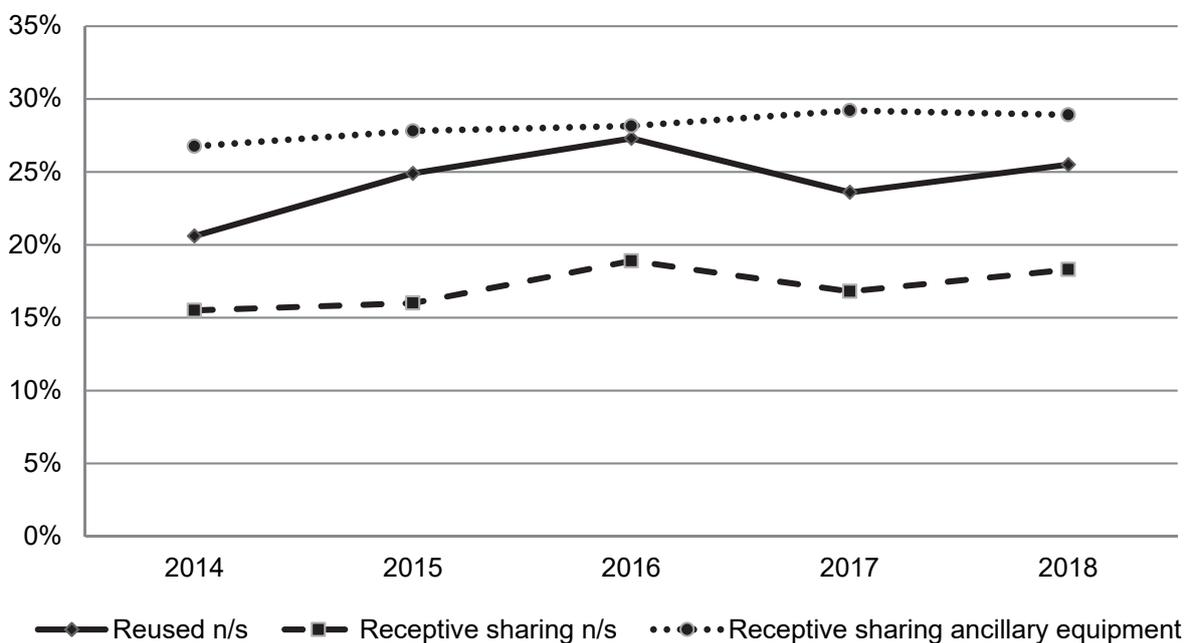

Figure 2. Proportion of respondents (%) reporting last injecting pharmaceutical opioids, methadone, and performance and image enhancing drugs, 2014–2018

Daily or more frequent injection was reported by approximately half of respondents in all of the past five years (Table 1.1.2). Prevalence of at least one public injection (injection in a car, beach, park, street or squat) in the month prior to survey completion increased significantly from 36% in 2014 to 46% in 2018 (χ^2 trend $p<0.001$, Table 1.1.3). In 2018, almost one in five respondents reported they had experienced a drug overdose in the previous 12 months ($n=520$, 19%, Table 1.1.2), also reflecting a significant increase over the period 2014 (15%) to 2018 (19%) (χ^2 trend $p<0.001$).

As shown in Figure 3, there was a significant increase in two of the three key injecting risk behaviours over the five-year period 2014 to 2018. The proportion of respondents who reported reuse of needles and syringes (including one’s own) in the month preceding the survey increased, from 21% in 2014 to 26% in 2018 (χ^2 trend $p=0.023$). There was also a significant increase in the prevalence of receptive sharing of needles and syringes in the month prior to survey completion, from 16% in 2014 to 18% in 2018 (χ^2 trend $p=0.034$). Receptive sharing of ancillary equipment was stable over the period 2014 to 2018 (range 27% to 29%, χ^2 trend $p=0.157$). As in previous years, spoons and water were the most commonly identified receptively shared ancillary items in 2018 (Table 1.1.3).

Figure 3. Proportion of respondents (%) reporting reuse and receptive sharing of needles and syringes and receptive sharing of ancillary equipment in the last month, 2014–2018

Sexual behaviour

In all years 2014 to 2018 approximately half of respondents reported sex with a regular partner in the month prior to survey completion (range 43% to 47%, Table 1.1.6). Of these, the majority (72% to 77%) reported that they did not use condoms with their regular sex partner. A smaller proportion of respondents (13% to 15%) reported sex with other partners in the month preceding survey participation. Condom use was higher among this group, with approximately two fifths reporting some condom use and one quarter reporting always using condoms with non-regular partners in the 2018 survey. The proportion of respondents reporting sex work in the month prior to the survey remained low and stable at 4% to 6% over the last five years (χ^2 trend $p=0.491$) and the use of condoms at last paid sex was relatively high at between 62% and 71% in all years between 2014 and 2018 (Table 1.1.6). Of the respondents who reported sex work in the previous month in 2018 ($n=154$), 53% were women, 44% were men, and 3% identified as transgender.

Drug treatment

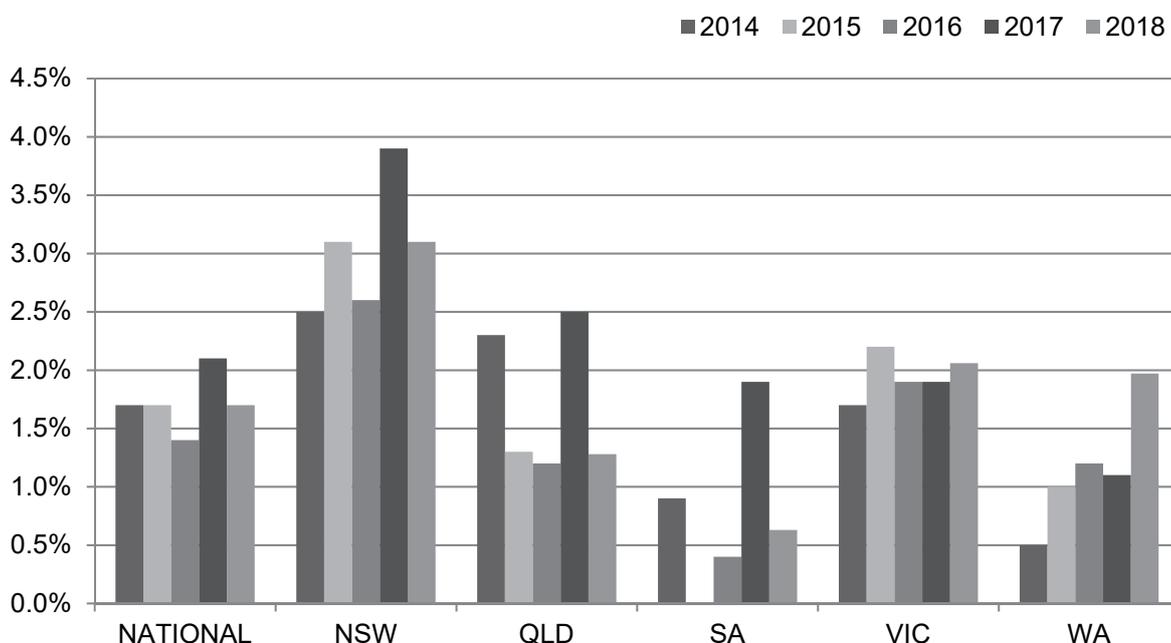

Engagement with drug treatment services was high (Table 1.1.4), with two thirds (69%) of respondents reporting a lifetime history of drug treatment in 2018. Nonetheless, there was a significant decline in the overall proportion of respondents reporting current opioid substitution therapy (OST; methadone, buprenorphine or buprenorphine-naloxone treatment) from 38% in 2014 to 31% in 2018 (χ^2 trend $p < 0.001$). This may reflect a significant increase in the proportion of respondents reporting methamphetamine as the last drug injected (from 33% to 48% 2014-2018) with OST not indicated for methamphetamine dependence. However, current OST among respondents who reported last injecting opioids was stable over the period 2014 to 2018 (range 48% to 49%, χ^2 trend $p = 0.984$). In 2018, current methadone maintenance treatment was reported by 21% of respondents, with current buprenorphine treatment reported by 7% of respondents and buprenorphine-naloxone treatment by 8% of respondents.

HIV antibody prevalence

HIV antibody prevalence remained low and stable nationally over the period 2014 to 2018 (range 1.4% to 2.1%, χ^2 trend $p = 0.641$, Table 1.2.1). At the jurisdictional level (Figure 4), HIV antibody prevalence was also low and stable.

No respondents in the Northern Territory, Tasmania or the Australian Capital Territory, and no women in South Australia tested positive to HIV antibodies in any of the previous five years, 2014 to 2018.

Figure 4. HIV antibody prevalence (%) by jurisdiction, 2014–2018

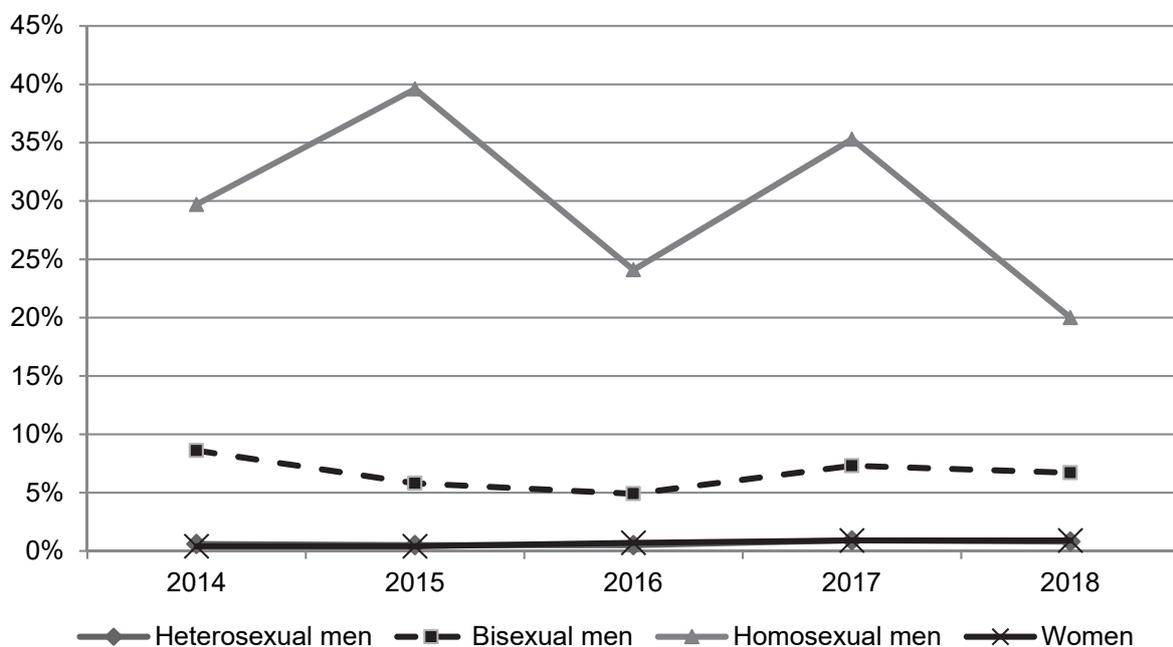

Nationally, across all survey years, HIV antibody prevalence was consistently higher among homosexual male respondents than among bisexual and heterosexual male respondents or female respondents (Table 1.2.2 and Figure 5). In the last five years (2014 to 2018), HIV prevalence was also higher among men who reported methamphetamine as the last drug injected (3.0% in 2018)

compared to men who reported last injecting other drugs (2.4% in 2018, Table 1.2.4). In the four years from 2014 to 2017 HIV prevalence was higher among men who reported sex work in the month preceding the survey compared to men who did not report recent sex work. However, in 2018 there was no significant difference in HIV prevalence between men who reported recent sex work and men who did not (Table 1.2.10)⁵.

In 2018, respondents from an Aboriginal and/or Torres Strait Islander background were significantly more likely to test HIV antibody positive than non-Indigenous respondents (3.6% vs 1.1% respectively, $p < 0.001$). However, prevalence of HIV infection among Aboriginal and Torres Strait Islander respondents was stable between 2014 and 2018 (2.0% in 2014 to 3.6% in 2018, χ^2 trend $p = 0.093$). Of the $n = 19$ Indigenous respondents who tested HIV antibody positive in 2018, 53% ($n = 10$) identified as heterosexual.

Figure 5. HIV antibody prevalence (%) by gender and sexual identity, 2014–2018

In 2018, the median age of HIV antibody positive respondents was 46.5 years (range 24-63 years) and respondents first injected a median of 16 years prior to survey participation (range 1-41 years). In 2018, there was no difference in the median age ($p = 0.316$) or the median time since first injection ($p = 0.166$) among HIV positive and HIV negative respondents.

HCV antibody prevalence

HCV antibody prevalence declined nationally from 54% in 2014 to 45% in 2018 (χ^2 trend $p < 0.001$, Table 1.3.1). Over the five-year period 2014 to 2018, HCV antibody prevalence declined among men (from 53% in 2014 to 46% in 2018, χ^2 trend $p = 0.002$) and among women (from 56% in 2014 to 43% in 2018, χ^2 trend $p < 0.001$). At the jurisdictional level (Figure 6), HCV antibody prevalence remained stable over the period 2014 to 2018, including among men and women in five of the eight jurisdictions. However, decreases in HCV antibody prevalence were observed in NSW (total $p = 0.011$, women $p = 0.018$), SA (women $p = 0.049$) and WA (total $p = 0.006$, men $p = 0.029$). Across all

five years of the survey, HCV antibody prevalence was significantly higher among older respondents and those with longer injection histories (Table 1.3.3 and 1.3.4). Figure 7 illustrates the relationship between exposure to HCV and time since first injection among respondents in 2018.

Figure 6. HCV antibody prevalence (%) by jurisdiction, 2014–2018

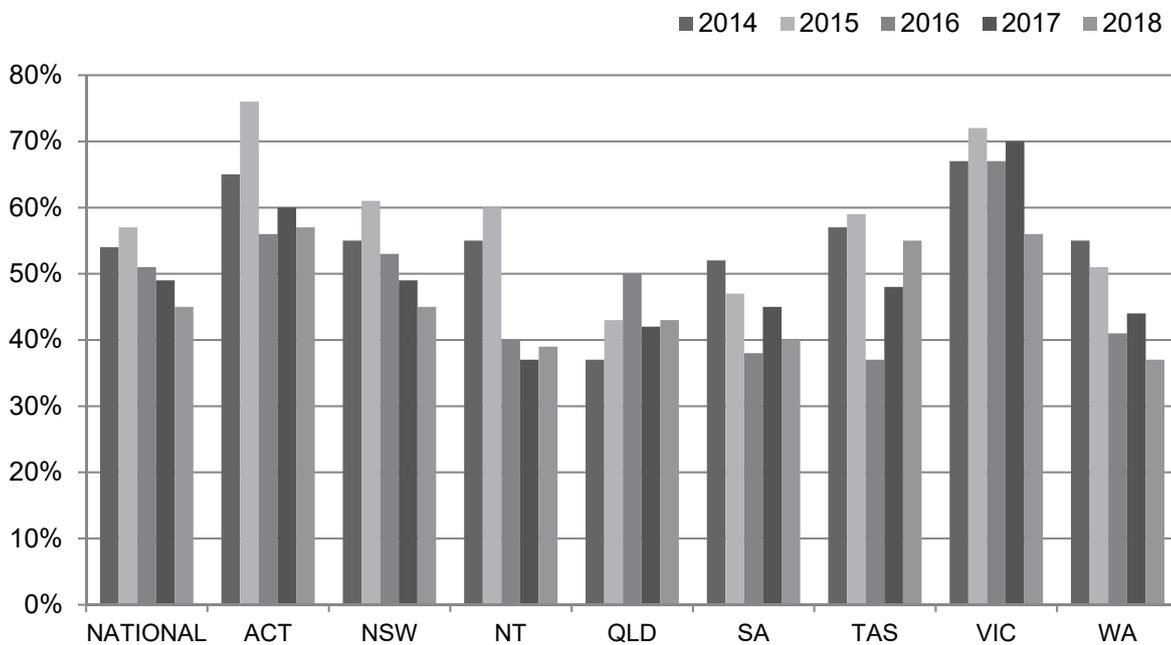

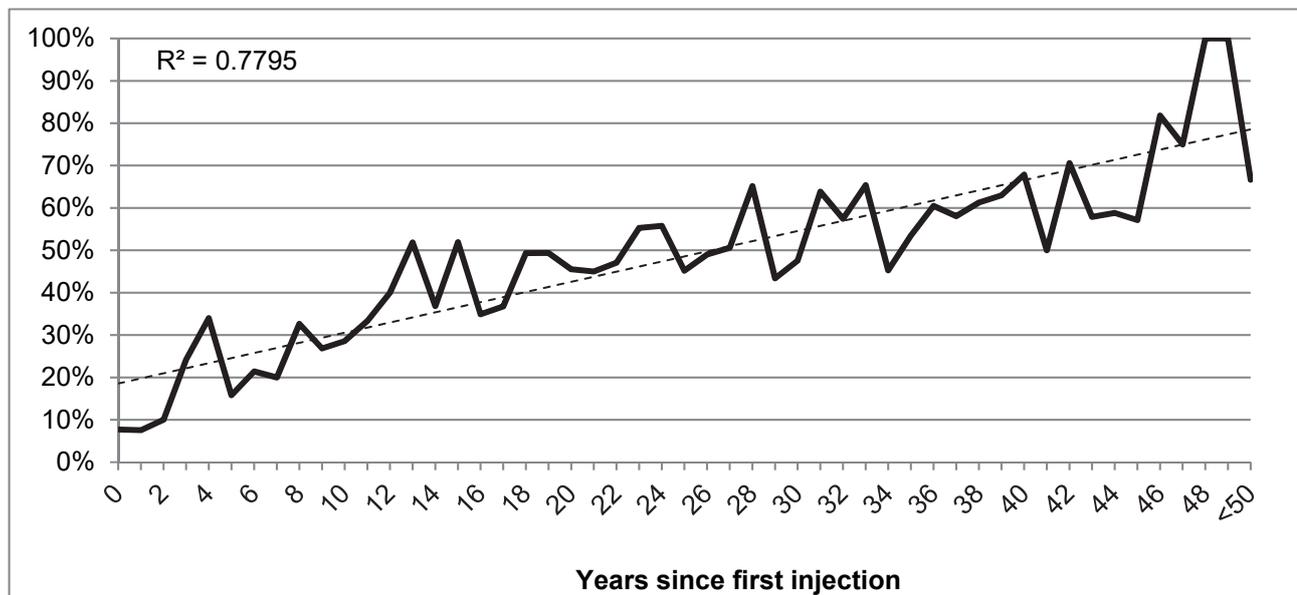

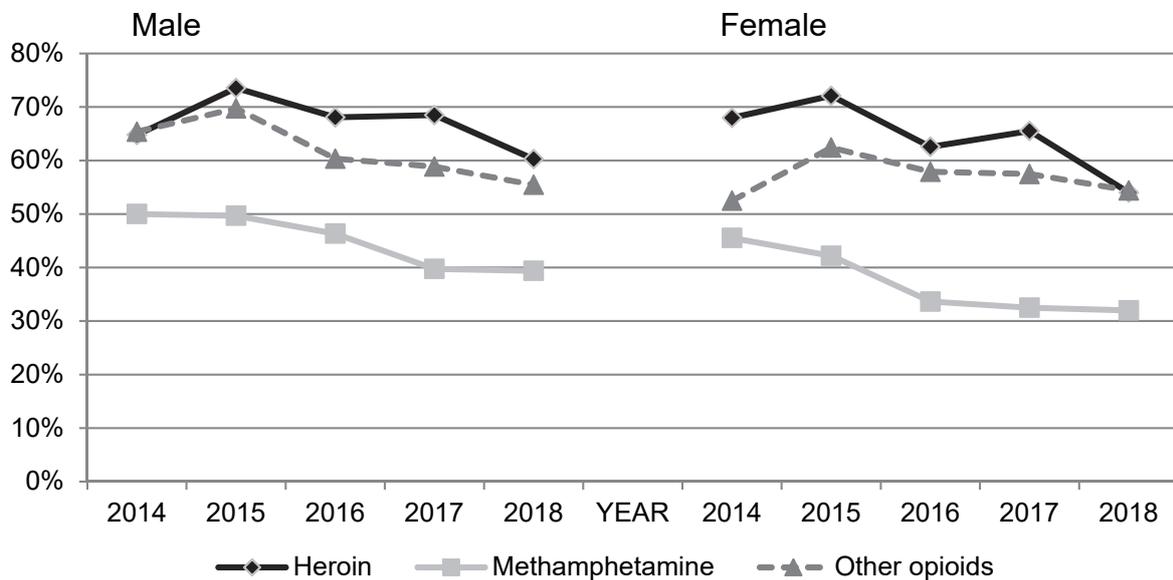

Figure 7. HCV antibody prevalence (%) by time since first injection, 2018

In all survey years, prevalence of HCV was also higher among respondents reporting heroin or other opioids as the last drug injected compared to respondents who last injected methamphetamine (Figure 8). HCV antibody prevalence was also consistently higher among respondents who reported imprisonment in the year preceding survey completion compared to those who did not ($p < 0.001$ in

all years 2014 to 2018) and among respondents who reported receptive syringe sharing in the last month compared to respondents who did not ($p < 0.05$ in 2014, 2015, 2017 and 2018).

Figure 8. HCV antibody prevalence (%) by drug last injected and gender, 2014–2018

HIV and HCV testing

Prevalence of HIV diagnostic screening among ANSPS respondents over the period 2014 to 2018 was high, with 81% to 85% reporting a lifetime history of HIV diagnostic testing (Table 1.1.5). In 2018, 50% of respondents reported an HIV diagnostic test in the previous 12 months. Among the $n=46$ respondents who tested HIV antibody positive, almost two thirds (63%, $n=29$) were aware of their HIV positive status. A minority (13%, $n=6$) of respondents who tested HIV positive reported that they were HIV negative, 7% ($n=3$) reported they did not know their HIV status and 17% ($n=8$) did not report their HIV status.

Respondents also reported high prevalence of lifetime HCV diagnostic screening over the period 2014-2018 (range 80% to 88%). In 2018, just over half (53%) of respondents reported an HCV diagnostic test in the previous 12 months.

HCV treatment uptake

Among respondents who tested HCV antibody positive and after excluding those who reported spontaneous HCV clearance, the proportion who reported a lifetime history of HCV treatment increased significantly, from 13% in 2014 to 55% in 2018 (χ^2 trend $p < 0.001$, Figure 9). Similarly, among respondents who tested HCV antibody positive and after excluding those who reported spontaneous or treatment-induced clearance more than 12 months previously, the proportion who reported recent (last 12 months) HCV treatment increased significantly from 1% in 2014 to 39% in 2018 (χ^2 trend $p < 0.001$). As shown in Figure 10, there was an increase in the proportion of respondents reporting a lifetime history of HCV treatment over the period 2014 to 2018 in all jurisdictions except the Northern Territory.

Figure 9. Proportion of respondents (%) reporting lifetime and recent HCV treatment among HCV antibody positive respondents, 2014–2018

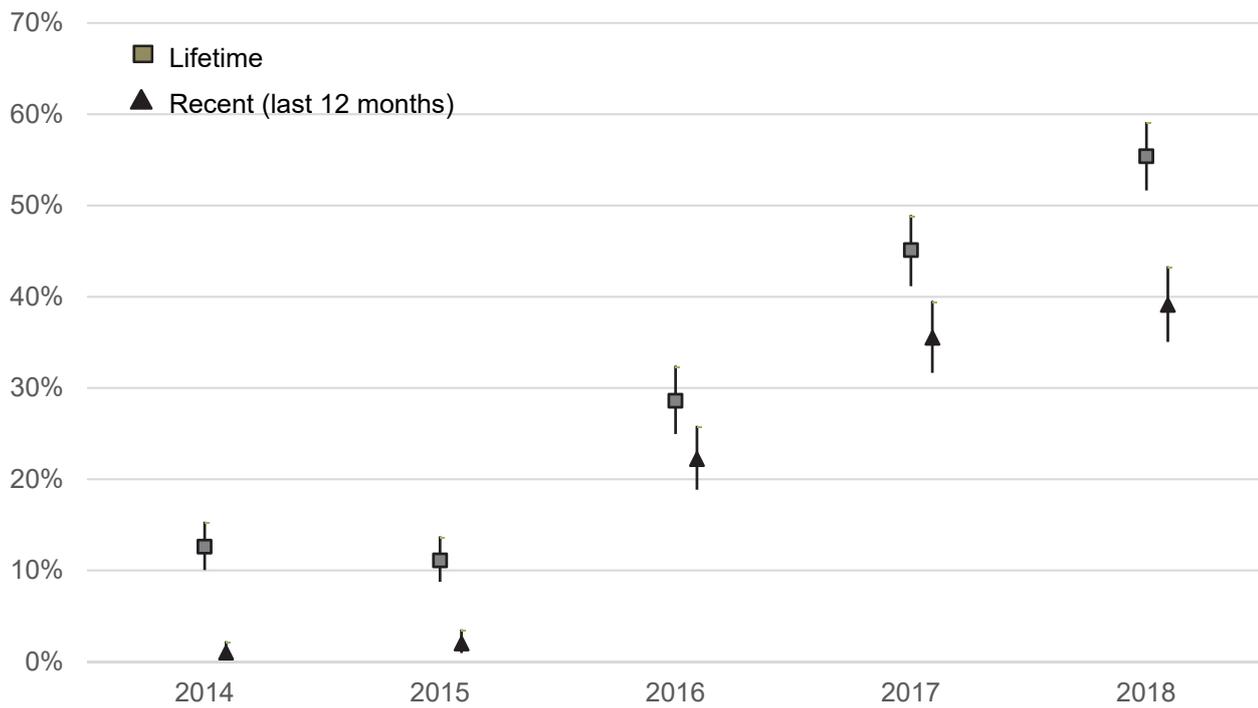

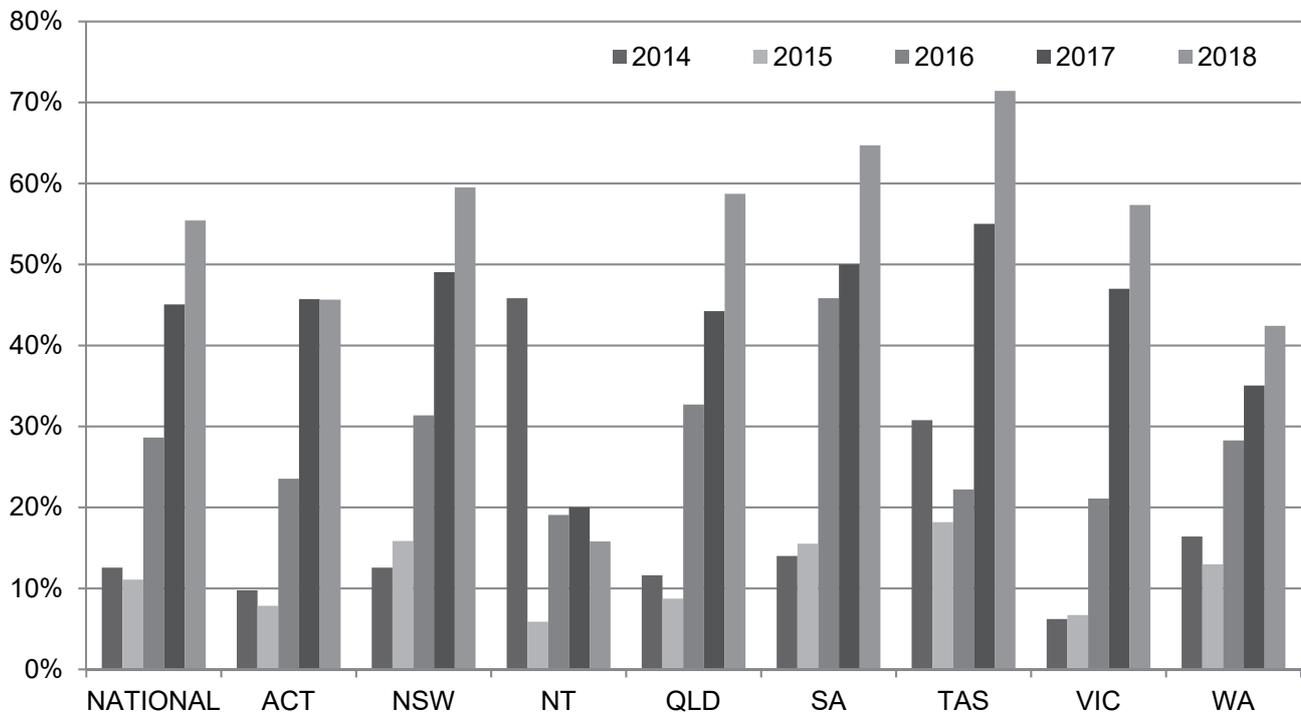

Figure 10. Lifetime history of HCV treatment (%) nationally and by jurisdiction, 2014–2018

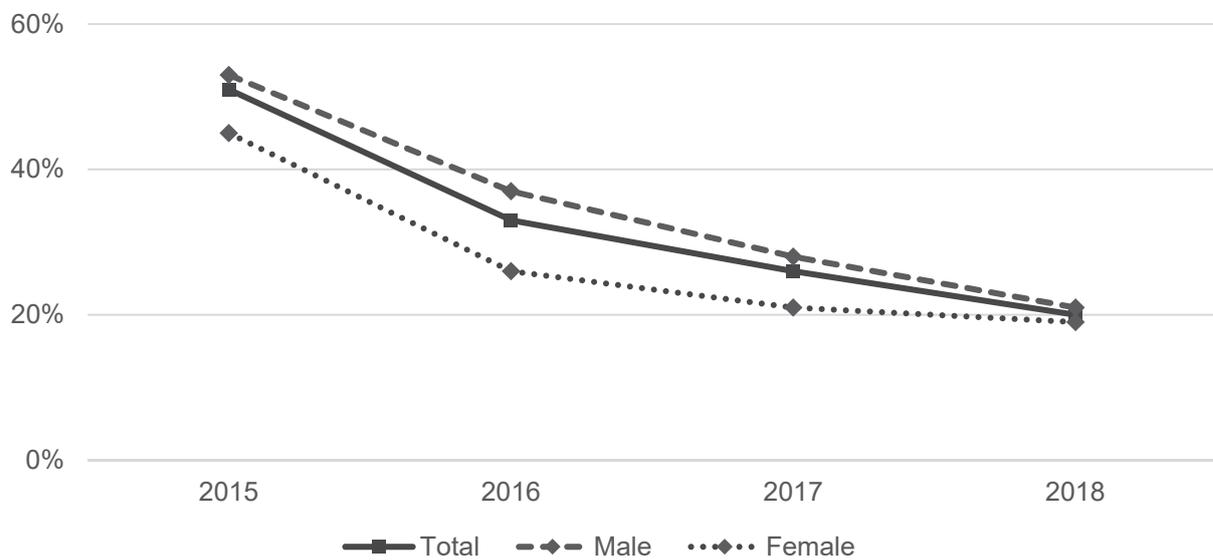

HCV RNA prevalence

Given universal access to HCV Direct Acting Antiviral (DAA) therapy through the Australian Government’s Pharmaceutical Benefits Scheme (PBS) from March 2016 and a projected increase in treatment uptake⁶, the ANSPS commenced HCV RNA testing, in addition to antibody testing in 2015 (Tables 1.4.1 to 1.4.11). Laboratory procedures are detailed in the Methodological Notes (Appendix B). It should be noted that only a sub-sample of respondents had sufficient DBS samples for HCV RNA testing. Weightings were therefore applied to account for potential sample bias among the subset eligible for RNA testing with respect to gender (given higher rates of spontaneous clearance among women) and HCV antibody status. Further, results with small sample sizes, particularly at the jurisdictional level, should be interpreted with caution.

As previously stated, HCV antibody prevalence declined significantly (from 54% in 2014 to 45% in 2018, χ^2 trend $p < 0.001$) and lifetime HCV treatment increased significantly (from 13% in 2014 to 55% in 2018, χ^2 trend $p < 0.001$). Among respondents who were tested for HCV RNA (range 35%-62% of overall sample), the proportion with detectable HCV RNA (active infection) also declined significantly, from 51% in 2015 to 20% in 2018 (χ^2 trend $p < 0.001$). As shown in Figure 11, HCV RNA prevalence declined significantly among both males (53% in 2015 to 21% in 2018, χ^2 trend $p < 0.001$) and females (45% in 2015 to 19% in 2018, χ^2 trend $p < 0.001$).

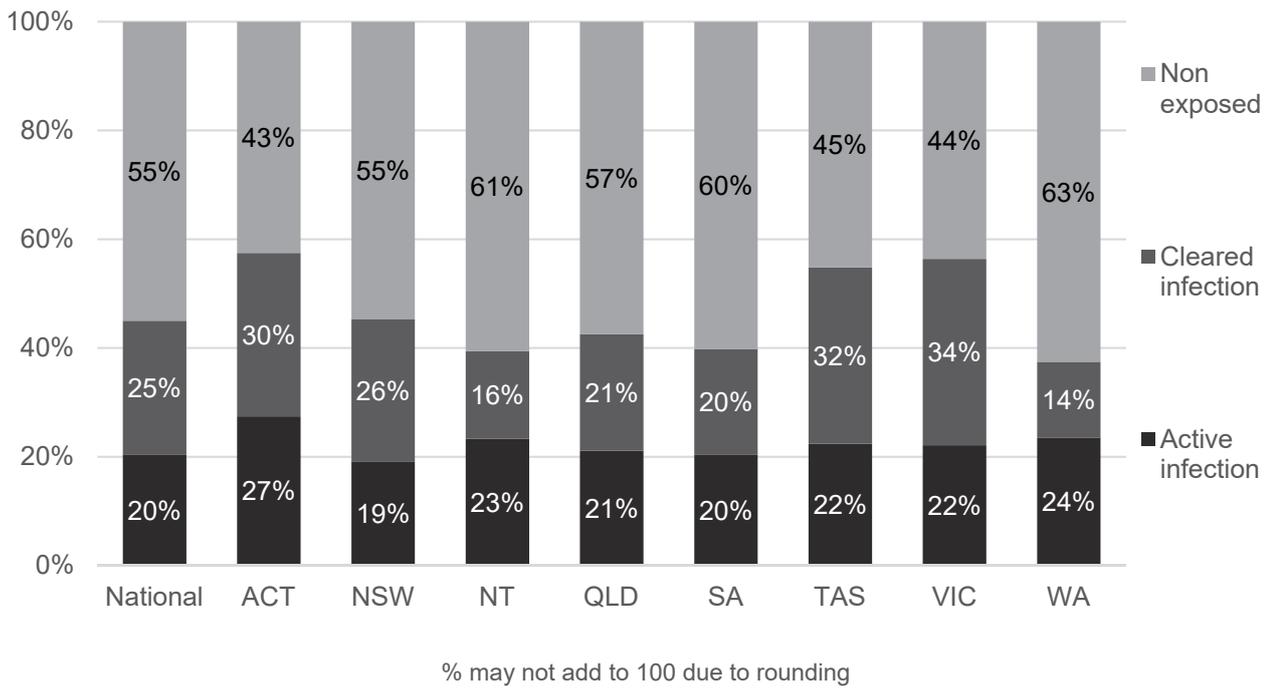

Figure 11. Proportion of respondents (%) with detectable HCV RNA by gender, 2015–2018*

* Weighted for gender and HCV antibody status

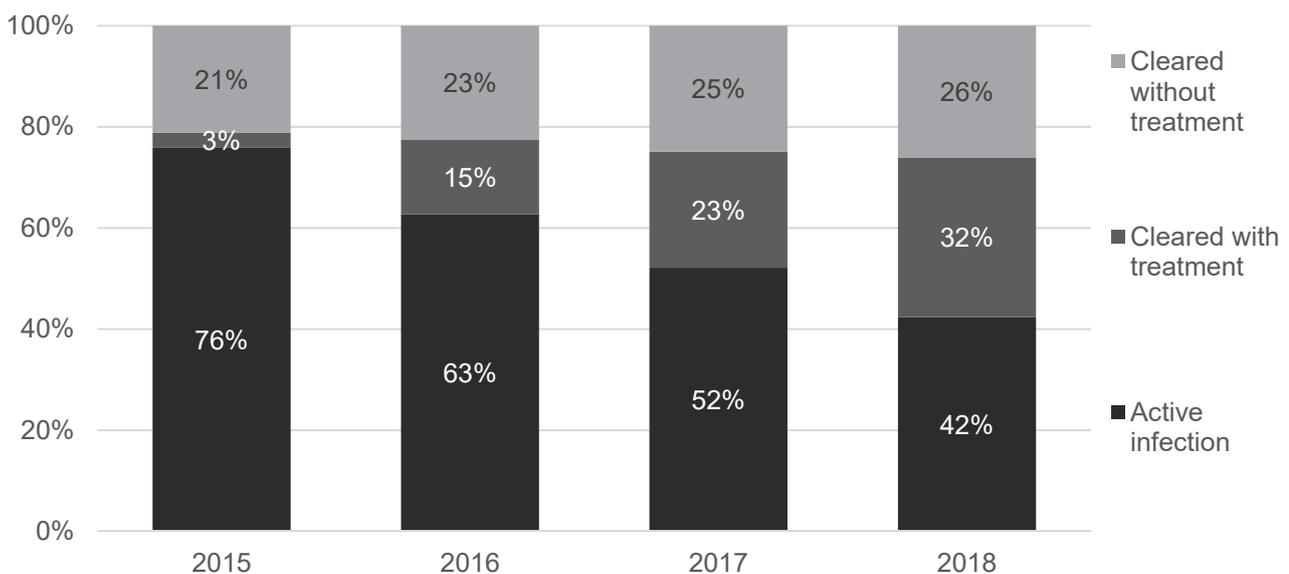

Results of HCV antibody and RNA testing can be combined to provide an estimate of the viraemic status among respondents⁶. As shown in Figure 12, the proportion of respondents with evidence of exposure to HCV was 45% nationally in 2018 and varied from 37% (Western Australia) to 56% (Victoria) at the jurisdictional level. After accounting for both spontaneous and treatment-related viral clearance, the proportion of respondents with active HCV infection was 20% nationally and <30% in all jurisdictions in 2018.

Figure 12. HCV viraemic status (%) nationally and by jurisdiction in 2018

Among respondents who tested HCV antibody positive, the proportion who spontaneously cleared the virus was stable at between 21%-26% over the period 2015 to 2018 (χ^2 trend $p=0.090$, Figure 13). The proportion of HCV antibody positive respondents who had cleared the virus with treatment increased from 3% in 2015 to 32% in 2018 (χ^2 trend $p<0.001$), while the proportion of respondents with active HCV infection declined from 76% in 2015 to 42% in 2018 (χ^2 trend $p<0.001$).

Figure 13. HCV viraemic status (%) among HCV antibody positive respondents nationally, 2015 to 2018

Appendix B: Methodological notes

Capillary blood was obtained by finger-prick using disposable lancets and cotton-fibre blotting paper. Dried blood samples were kept at room temperature at the survey sites and couriered to a central laboratory every second or third day. HIV antibody was detected using the Murex 1.2.0 ELISA (Diasorin). Repeatedly reactive specimens were subjected to Western blot confirmatory testing (Bio-Rad New LAV blot 1, France). A modified third generation enzyme immunoassay (Monolisa anti-HCV Plus Version 3 EIA, Biorad, France) was used to test for HCV antibody. A modified cut off value for optical density was calculated to capture greater than 95% of the seronegative population. Specimens were considered positive for HCV antibody if the optical density to cut off ratio was greater than or equal to one on initial and subsequent testing.

In 2015, HCV RNA was detected and quantified using a modified Abbott RealTime™ (Illinois, United States) HCV RNA assay. The Abbot RealTime HCV RNA assay involves specimen extraction automation using the Abbott M2000SP coupled with the M2000RT Realtime PCR instrument. A bias (+1.91 Log₁₀) applied post run gave a quantifiable DBS HCV viral load (VL) result with a lower limit of detection of 977IU/mL (plasma equivalency). A qualitative result of <12IU/mL detected (trace/equivocal) was applied to samples <977IU/mL (plasma equivalency).

In all subsequent years (2016-2018), HCV RNA was detected and quantified on the Hologic Panther™ using the Aptima™ HCV Quant Dx assay (Hologic, Inc. San Diego, Calif) which has a limit of quantitation (LOQ) 10 IU/mL and an upper limit of quantitation of 10⁸ IU/mL in plasma. An offboard DBS elution protocol was applied prior to sampling. To correct for haematocrit, all post run DBS VL results on the Aptima assay were multiplied by a plasma conversion factor of 36.36. This calculation was based on the following assumptions: 45% haematocrit average per DBS, 50uL DBS volume and 1000ul Aptima transport media volume. A qualitative result of <10IU/mL detected (trace/equivocal) was applied to samples <400IU/mL (plasma equivalency).

Data presented in this report were analysed using Stata, Version 14 (Stata Corporation, College Station TX). Temporal changes in HIV/HCV antibody and HCV RNA prevalence were assessed using the X^2 test for linear trend. Associations between demographic and behavioural variables and HIV/HCV antibody and HCV RNA prevalence were assessed using the X^2 test or Fisher's exact test where expected frequencies were less than five. It should be noted that only a sub-sample of respondents had sufficient DBS sample for HCV RNA testing. HCV RNA tables were weighted to account for sample bias with respect to HCV antibody status and gender. Weights were applied to national data and to each individual jurisdiction, such that jurisdictional HCV RNA results will not necessarily add to data presented at the national level. Further, results with small sample size, particularly at the jurisdictional level, should be interpreted with caution.

Percentage values in tables may not add to 100 due to rounding. Totals in HIV and HCV antibody prevalence tables stratified by gender include people whose gender was not reported or reported as transgender. Time since first injection was calculated by subtracting age at first injection from age at survey completion. Totals in HIV and HCV antibody prevalence tables stratified by time since first injection include people who did not report age at survey completion or age at first injection. Tables reporting HIV antibody prevalence stratified by demographic and drug use characteristics are not included in this report for states and territories or survey years where the number of HIV antibody positive participants was less than 5 in all years.

Where data were collected but no participants endorsed a particular response, results are presented as "0 (0)". The symbol "--" shown in some tables denotes missing data; and is used to identify circumstances where data were not collected in the reported format. The vast majority of survey questions were consistent over all survey years.

NSP staff recorded sex, age group and survey participation for all clients at the NSP during the survey period and this data was used to assess response rates. Some clients visited the site more than once during the survey week, and only one attendance per person was included in the response rate denominator. Ethical approvals for the study were obtained from Human Research Ethics Committees associated with the investigators and participating sites. Verbal rather than written informed consent was obtained to assure the anonymity of participants.

Appendix C: List of Tables

1. Demographic characteristics and drug use

Table 1.1.1	Number (percentage) of respondents by demographic characteristics and survey year
Table 1.1.2	Number (percentage) of respondents by last drug injected, frequency of injecting and survey year
Table 1.1.3	Number (percentage) of respondents by injecting behaviour in the last month and survey year
Table 1.1.4	Number (percentage) of respondents by treatment for drug use and survey year
Table 1.1.5	Number (percentage) of respondents by testing for HIV and HCV, HCV treatment by survey year
Table 1.1.6	Number (percentage) of respondents by sexual behaviour in the month prior to survey and survey year

2. HIV antibody prevalence
