ACKNOWLEDGEMENTS

We would like to acknowledge the many people who assist each year in the development and conduct of the Australian NSP Survey (ANSPS), particularly the clients, staff and managers at participating NSP services. We also appreciate the dedication and vision of the founding members of the project and the late Dr Margaret MacDonald who was responsible for the development and conduct of the ANSPS from 1995 until 2003.

Special thanks go to Mr Philip Cunningham, Senior Scientist and Operations Manager, Ms Beth Catlett, DBS Coordinator and Mr Mitchell Starr, Senior Hospital Scientist at the NSW State Reference Laboratory for HIV at St Vincent's Hospital and St Vincent's Centre for Applied Medical Research. We also appreciate the assistance provided by Ms Louise Geddes and Ms Rachel McCleave from the Kirby Institute.

In 2020, the project received support and input from the following members of the ANSPS National Advisory Group: Ms Jennifer Taleski (ACT); Ms Elisabeth Morgan (NSW); Mr David Decolongon (NT); Mr Stephen Lymb, Mr Bruce Surman and Mr Rob Gerrie (SA); Ms Myf Briggs (TAS); Mr Gary Morris and Ms Terrie Spall (VIC); Ms Jude Bevan (WA); Ms Melanie Walker (Australian Injecting and Illicit Drug Users League); and Ms Sue Heard, Dr Jenny Iversen and Professor Lisa Maher (Kirby Institute). We would particularly like to thank Mr Robert Kemp (QLD) for chairing the National Advisory Group.

Ethical approvals were obtained from institutional ethics committees associated with the investigators and participating NSP sites. The Australian Needle Syringe Program Survey is funded by the Australian Government Department of Health.

KEY FINDINGS

- The Australian NSP Survey (ANSPS) functions as a strategic early-warning system designed to monitor blood borne viral infections and injecting and sexual behaviour among people who inject drugs.
- In 2020, 38 Needle Syringe Programs (NSPs) throughout Australia participated in the ANSPS and 1,324 NSP attendees completed the survey. The response rate was 35%.
- The number of participating NSPs, number of respondents and the response rate in 2020 were lower than in previous years due to public health responses to the COVID-19 pandemic. Further, Victorian NSP services were not in a position to implement the ANSPS in 2020 due to a range of restrictions designed to reduce community transmission of COVID-19 during the ANSPS data collection period.

COVID-19

- As a sentinel surveillance system with the capacity to respond to emerging issues, the 2020 ANSPS included a module about COVID-19-related impacts.
- The majority (78%) of respondents reported that it was not more difficult to access needles and syringes during the pandemic, while one in two reported no change to their illicit drug use.
- Almost one in three respondents reported they had been tested for COVID-19, with the majority (96%) reporting a negative result. Among the remaining respondents, four reported a positive test result, six were unsure of the result, and five did not report their test result.

Demographic characteristics

- Over the period 2016 to 2020, the median age of survey respondents was stable (range 42 to 43 years), with the proportion of young injectors (aged <25 years) also stable (range 3% to 5%).
- The median time since first injection was stable between 2016 and 2020 (range 21 to 22 years), and the proportion of new initiates (those injecting for less than three years) was also stable between 2016 and 2020 (range 5% to 6%).
- The proportion of respondents from an Indigenous Australian background increased, from 18% in 2016 to 22% in 2020.
- The proportion of respondents reporting incarceration in the 12 months prior to survey completion was stable over the five-year period 2016 to 2020 (range 12% to 13%).
- While the proportion of respondents reporting sex work in the month prior to the survey remained low and stable at 5% to 6% over the last five years, condom use at last paid sex declined from 68% in 2016 to 44% in 2020.

Injection behaviour

- One in two respondents reported injecting daily or more frequently in all survey years between 2016 and 2020.
- The proportion of respondents reporting methamphetamine as the last drug injected increased from 43% in 2016 to 47% in 2020. Methamphetamine was the most commonly reported drug last injected nationally in all years 2016 to 2020.
- While the proportion of respondents reporting heroin as the last drug injected declined from 28% in 2016 to 22% in 2020, this decline was not evident when data from Victoria were excluded.
- Pharmaceutical opioids were the third most commonly reported class of drugs last injected in all years 2016 to 2020, and prevalence declined from 8% to 6% over this period.

- The proportion of respondents who reported last injecting performance and image enhancing drugs (PIEDs) was low and stable between 2016 to 2020 (range 4% to 6%).
- There was a decline in the proportion of respondents reporting receptive sharing of needles and syringes in the last month, from 19% in 2016 to 16% in 2020. The proportion reporting recent (last month) reuse of needles and syringes (including reuse of one's own syringes) also declined, from 27% in 2016 to 23% in 2020, while prevalence of recent receptive sharing of drug preparation equipment remained stable at between 25% and 30% over the same period.
- The prevalence of self-reported drug overdose in the past 12 months declined, from 18% in 2016 to 13% in 2020.

Drug treatment

- Engagement with drug treatment services remained high, with two thirds (65%) of respondents reporting a lifetime history of drug treatment in 2020.
- Although there was a decline in the overall proportion of respondents who reported current engagement in opioid agonist therapy (OAT) between 2016 and 2020, engagement in OAT remained stable among respondents who reported last injecting an opioid (range 44% to 53%).

HIV antibody prevalence

- Although HIV antibody prevalence remained low nationally over the five-year period (2016 to 2020), HIV prevalence increased from 1.4% in 2016 to 2.5% in 2020.
- In all years 2016 to 2020 HIV antibody prevalence was higher among homosexual men compared to bisexual or heterosexual men and compared to women.

HCV antibody prevalence

- Hepatitis C virus (HCV) antibody prevalence declined nationally from 51% in 2016 to 39% in 2020. This is the fourth consecutive year that less than half of respondents had been exposed to HCV, following two decades of HCV antibody prevalence ≥50% (all years 1999 to 2016).
- Across all survey years 2016 to 2020, prevalence of HCV antibody was higher among older than among younger respondents and among those with longer injection histories.

HCV RNA prevalence

- Among respondents who were tested for HCV RNA and after applying weightings, the proportion with detectable HCV RNA (active infection) declined from 33% in 2016 to 16% in 2020. HCV RNA prevalence declined among both males (37% in 2016 to 17% in 2020) and females (26% in 2016 to 15% in 2020).

HCV treatment uptake

- Among respondents assessed as eligible for HCV treatment, the proportion who reported a lifetime history of HCV treatment increased, from 29% in 2016 to 62% in 2020.
- Similarly, among respondents assessed as eligible, the proportion who reported recent (last 12 months) HCV treatment increased from 22% in 2016 to 32% in 2020.
- Notwithstanding this overall increase, there was a decline in the proportion of respondents who reported recent HCV treatment in 2020 (32%) compared to 2019 (44%). There was also a decline in the proportion of respondents who reported a recent HCV diagnostic test in 2020 (48%) compared to 2019 (54%).

INTRODUCTION

The Australian Needle Syringe Program Survey (ANSPS) provides serial point prevalence estimates of human immunodeficiency virus (HIV) and hepatitis C virus (HCV) antibody prevalence, HCV ribonucleic acid (RNA) prevalence and sexual and injecting risk behaviour among people who inject drugs (PWID) in Australia. Conducted annually over a one-two week period in October, all clients attending participating Needle Syringe Program (NSP) services are invited to complete a brief, anonymous questionnaire and to provide a capillary blood sample for HIV and HCV testing (see methodological notes [Appendix B] for further details on the ANSPS design and implementation). Commencing in 2015, HCV RNA testing has also been conducted among respondents with sufficient dried blood spot (DBS) samples. This report presents national and state/territory findings for the period 2016 to 2020.

COVID-19

In Australia, a range of public health measures have been implemented since COVID-19 was declared a global pandemic by the World Health Organisation in March 2020. All Australian states and territories have experienced COVID-19-related travel restrictions, while most have restricted public and private gatherings, and some have introduced full or partial lockdowns during the pandemic. In order to provide flexibility and to accommodate jurisdictional differences in the pandemic response, the 2020 ANSPS was implemented in several phases rather than the usual mid-October time frame nationally. Four jurisdictions with little or no community transmission (WA, ACT, TAS, QLD) implemented the survey early (in September), while two jurisdictions (NSW and NT) implemented the ANSPS in the usual October timeframe. One jurisdiction (SA) implemented the ANSPS later than usual (in December), however SA experienced a snap lockdown the week before survey was due to be implemented and the ANSPS was completed off site (surveys taken away for completion) rather than on site. These factors resulted in a significantly reduced number of ANSPS respondents in this jurisdiction. Between June and November 2020 Victoria experienced outbreaks of community transmission of COVID-19 that necessitated the implementation of public health measures to reduce transmission and no Victorian NSP services were in a position to participate in the 2020 ANSPS.

Due to the impacts of the COVID-19 pandemic, a reduced number of NSP services participated in the 2020 ANSPS compared to previous years (38 sites in 2020 compared to 54 sites in 2019). Further, the number of ANSPS respondents halved from ~2,600 in 2019 to 1,324 in 2020 due to the limited participation of SA and the non-participation of Victoria. The response rate was also lower at 35% in 2020, compared to >40% between 2016 and 2019 (Table 1.1.1). Of the 1,324 ANSPS respondents in 2020, the majority (90%) were recruited from NSP services (n=31) that participated in the ANSPS in each of the past five years (2016 to 2020). Appendix A provides details of participating NSP services over the period 2016 to 2020.

As a sentinel surveillance system with the capacity to respond to emerging issues, the 2020 ANSPS included a module about the impacts of COVID-19. Among the overall 1,324 ANSPS respondents in 2020, 1,224 (92%) completed the ANSPS COVID-19 module that comprised a set of eight questions. The following discussion and data analysis excludes the 100 ANSPS respondents who declined to complete the COVID-19 module.

As a testament to NSP services' commitment to ensure service delivery during the COVID-19 pandemic, the majority of ANSPS respondents ($n=960$, 78%) reported that it was not more difficult to access needles and syringes during the pandemic. However, around one in ten respondents ($n=144$, 12%) reported that it was more difficult to access needles and syringes since the pandemic commenced, and 9% ($n=113$) reported they had not attempted to access needles and syringes since March 2020.

A total of fifty respondents (4%) reported they had commenced depot buprenorphine (Buvidal® or Sublocade®) since March 2020, while 116 respondents (10%) reported they had commenced takeaway doses of their OAT and 145 respondents (11%) reported they had injected their own OAT since the pandemic commenced. Among respondents who reported OAT prescription at the time of ANSPS participation ($n=334$), 8% had commenced depot buprenorphine, 30% had commenced takeaway doses of their OAT and 28% reported they had injected their own OAT since March 2020.

Since the pandemic commenced a total of 202 respondents (17%) reported accessing take-home Naloxone (an opioid agonist used to reverse the effects of opioid overdose). Among respondents who reported last injecting an opioid, one in four ($n=129$, 27%) reported accessing take-home Naloxone since March 2020.

Just over half of respondents ($n=643$, 54%) reported no change in their illicit drug use since the pandemic commenced, while one in ten ($n=125$, 11%) reported that their illicit drug use had increased and one in three ($n=416$, 35%) reported their illicit drug use had decreased.

Almost one in three ANSPS respondents ($n=337$, 28%) reported that they had a COVID-19 test in 2020. Of these, four respondents (1%) reported a positive COVID-19 test. The majority of respondents tested for COVID-19 reported a negative result ($n=322$, 96%), while six respondents (2%) were unsure of their result and five respondents (1%) did not report their test result.

Demographic characteristics

Approximately two thirds of survey respondents were male across all years 2016 to 2020. In 2020, the majority (79%) of respondents identified as heterosexual, while 10% identified as bisexual and 4% as homosexual (Table 1.1.1). Women were significantly more likely to identify as bisexual than men in each of the past five years (18% vs 5% respectively in 2020, $p<0.001$).

Over the period 2016 to 2020 the proportion of respondents from an Indigenous Australian background increased significantly, from 18% to 22% (χ^2 trend $p<0.001$)^{1,2}. In all years 2016 to 2020, the majority of respondents were born in Australia (range 86% to 88%), with the United Kingdom/Ireland (4%) and New Zealand (3%) the predominant countries of birth outside Australia in 2020. Most respondents also reported that their parents spoke English at home (range 92% to 95%) over the period 2016 to 2020.

Over the period 2016 to 2020, the median age at survey completion ranged from 42 to 43 years and the proportion of respondents aged <25 years (3% in 2020) was also stable (χ^2 trend $p=0.167$, Table 1.1.1). The median time since first injection ranged from 21 to 22 years and the proportion of new initiates (those injecting for less than 3 years) was stable, ranging from 5% in 2016 to 6%

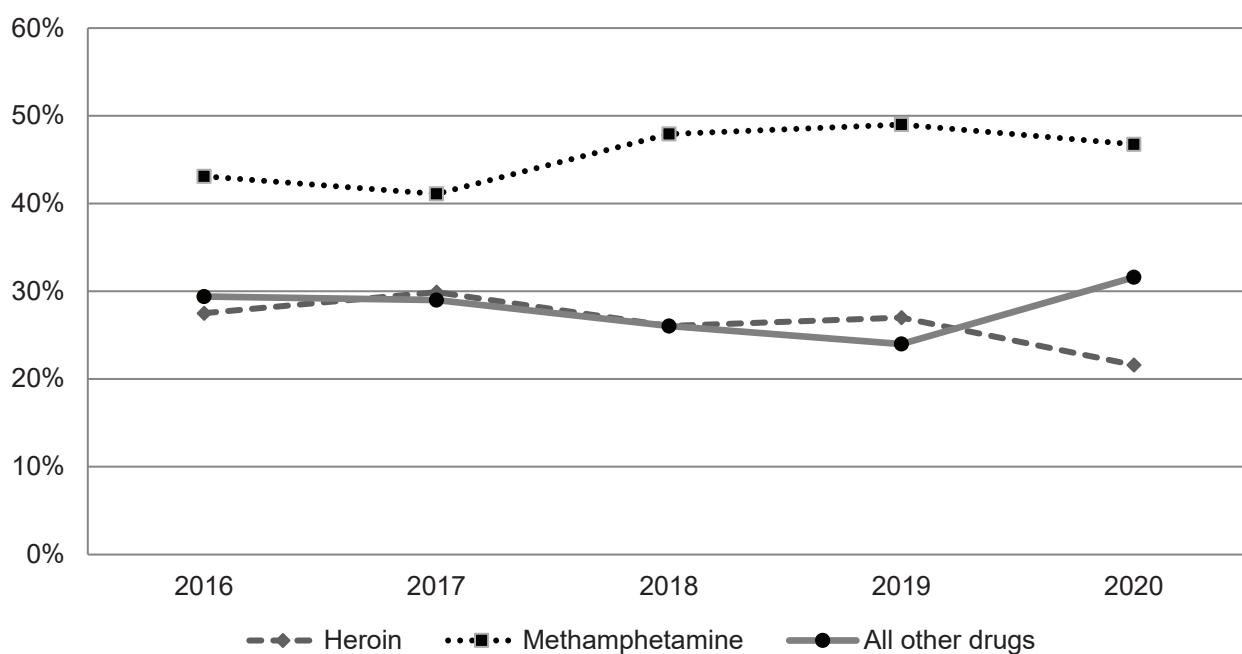

in 2020 (χ^2 trend $p=0.200$). The median age at first drug injection was stable across the period 2016 to 2020, ranging from 18 to 19 years of age. Among new initiates to injection drug use, the median age at first drug injection increased from 28 years in 2016 to 30 years in 2020.

The proportion of respondents reporting incarceration in the 12 months prior to survey completion remained stable, ranging from 12% to 13% over the five-year period 2016 to 2020 (χ^2 trend $p=0.472$). Among respondents with a history of recent incarceration, approximately one in three reported injecting while in prison and this proportion was stable over the period 2016 to 2020 (χ^2 trend $p=0.647$, Table 1.1.1).

Injection behaviour

Methamphetamine was the most commonly reported drug last injected nationally in all years 2016 to 2020 (Table 1.1.2). Reports of methamphetamine injection increased significantly over the five-year period, from 43% in 2016 to 47% in 2020 (χ^2 trend $p<0.001$, Figure 1). The significant increase in reports of methamphetamine injection over the five-year period (2016 to 2020) was also observed when data from Victoria were excluded (χ^2 trend $p=0.002$).

Figure 1. Proportion of respondents (%) reporting last injecting heroin, methamphetamine, and all other drugs, 2016–2020

Heroin was the second most commonly reported drug last injected nationally in 2020, with a significant decline in prevalence observed between 2016 (28%) and 2020 (22%, χ^2 trend $p<0.001$). However, this decline was not significant when data from Victoria (where opioids are the predominant drug last injected) were excluded (χ^2 trend $p=0.576$).

The third most commonly reported class of drugs last injected nationally was pharmaceutical opioids^{3,4} (8%, including morphine, oxycodone and fentanyl), with a significant decline observed over the period 2016 to 2020 (χ^2 trend $p=0.041$, Figure 2). The significant decline in pharmaceutical

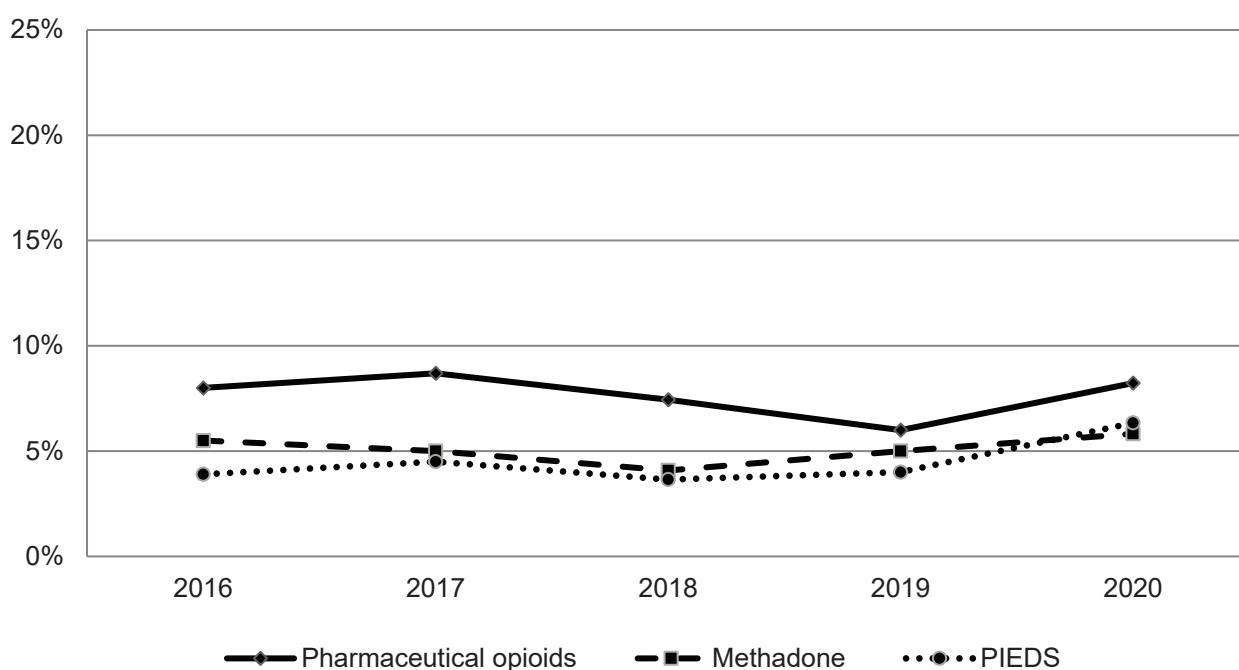

opioids as the last drug injected was also observed over the five-year period 2016 to 2020, when data from Victoria were excluded (χ^2 trend $p=0.004$).

Methadone was reported as the last drug injected by less than ten percent of ANSPS respondents in all years 2016 to 2020 (range 6% to 4%) with prevalence stable over this period (χ^2 trend $p=0.804$). Buprenorphine and buprenorphine-naloxone injection were reported by a minority of survey respondents. The prevalence of both buprenorphine-naloxone injection (2% to 1%, χ^2 trend $p=0.089$), and buprenorphine injection (2% to 3%, χ^2 trend $p=0.839$) was stable over the period 2016 to 2020.

A minority of survey respondents (1% across all survey years) reported cocaine as the last drug injected. The prevalence of performance and image enhancing drugs (PIEDs) as the last drug injected was stable over the period 2016 to 2020 (χ^2 trend $p=0.098$, Figure 2).

In all years 2016 to 2020, methamphetamine was the most commonly reported last drug injected among new initiates (less than 3 years since first injection), with a stable prevalence observed between 2016 and 2020 (range 48% to 63%, χ^2 trend $p=0.402$).

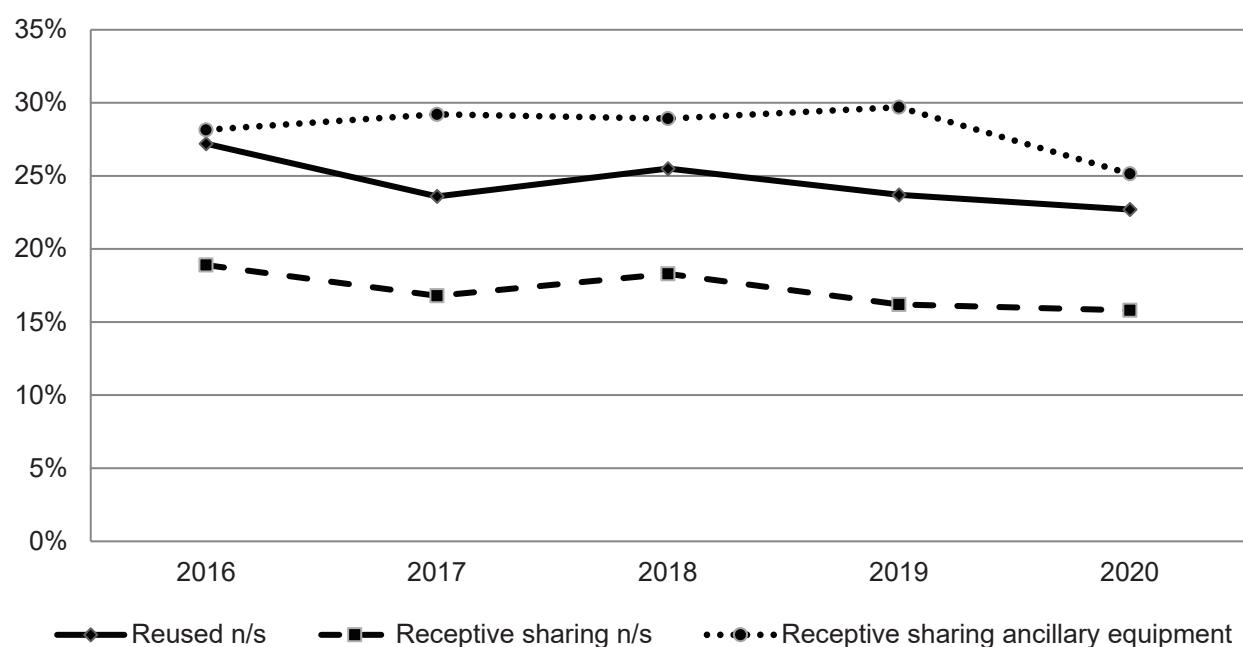

Figure 2. Proportion of respondents (%) reporting last injecting pharmaceutical opioids, methadone, and performance and image enhancing drugs, 2016–2020

Daily or more frequent injection was reported by approximately half of respondents in each of the past five years (Table 1.1.2). Prevalence of at least one public injection (injection in a car, beach, park, street or squat) in the month prior to survey completion was stable between 2016 to 2020 (range 42% to 47%, χ^2 trend $p=0.782$, Table 1.1.3). In 2020, almost one in eight respondents reported they had experienced a drug overdose in the previous 12 months (n=171, 13%, Table 1.1.2), and reports of overdose declined significantly over the period 2016 (18%) to 2020 (13%) (χ^2 trend $p=0.001$), including when data from Victoria were excluded (χ^2 trend $p=0.005$).

As shown in Figure 3, there was a significant decline in two of the three key injecting risk behaviours over the five-year period 2016 to 2020. The proportion of respondents who reported reuse of needles and syringes (including one's own) in the month preceding the survey declined, from 27% in 2016 to 23% in 2020 (χ^2 trend p=0.010). There was also a significant decline in the reports of receptive sharing of needles and syringes in the month prior to survey completion, from 19% in 2016 to 16% in 2020 (χ^2 trend p=0.023). Receptive sharing of ancillary equipment remained stable over the period 2016 to 2020 (range 25% to 30%, χ^2 trend p=0.381). As in previous years, spoons and water were the most commonly identified receptively shared ancillary items in 2020 (Table 1.1.3).

Figure 3. Proportion of respondents (%) reporting reuse and receptive sharing of needles and syringes and receptive sharing of ancillary equipment in the last month, 2016–2020

Sexual behaviour

In all years 2016 to 2020 approximately half of respondents reported sex with a regular partner in the month prior to survey completion (range 43% to 47%, Table 1.1.6). Of these, the majority (72% to 77%) reported that they did not use condoms with their regular sex partner. A smaller proportion of respondents (13% to 15%) reported sex with other partners in the month preceding survey participation. Condom use was higher among this group, with 22% reporting always using condoms and 28% reporting some condom use with non-regular partners in 2020. While the proportion of respondents reporting sex work in the month prior to the survey remained low and stable at 5% to 6% over the last five years (χ^2 trend p=0.391), condom use at last paid sex declined from 68% in 2016 to 44% in 2020 (χ^2 trend p<0.001, Table 1.1.6). Of the respondents who reported sex work in the previous month in 2020 (n=61), 52% were women, 44% were men, and 3% identified their sex as other.

Drug treatment

Engagement with drug treatment services was high (Table 1.1.4), with two thirds (65%) of respondents reporting a lifetime history of drug treatment in 2020. Nonetheless, there was a significant decline in the overall proportion of respondents reporting current OAT from 33% in 2016 to 26% in 2020 (χ^2 trend $p<0.001$). This decline was also observed when data from Victoria were excluded (χ^2 trend $p=0.012$). This may reflect the significant increase in the proportion of respondents reporting methamphetamine as the last drug injected, with OAT not indicated for methamphetamine dependence. Further, among respondents who reported last injecting opioids, current OAT was stable over the period 2016 to 2020 (range 44% to 53%, χ^2 trend $p=0.965$). In 2020, current methadone treatment was reported by 18% of respondents, with current buprenorphine treatment reported by 8% of respondents and buprenorphine-naloxone treatment by 5% of respondents.

HIV and HCV diagnostic testing

Prevalence of HIV diagnostic screening among ANSPS respondents over the period 2016 to 2020 was high, with 79% to 83% reporting a lifetime history of HIV diagnostic testing (Table 1.1.5). In 2020, 45% of respondents reported an HIV diagnostic test in the previous 12 months. Among the n=32 respondents who tested HIV antibody positive, the majority (88%, n=28) were aware of their HIV positive status. A minority (6%, n=2) of respondents who tested HIV positive reported that they were HIV negative, and 6% (n=2) did not report their HIV status.

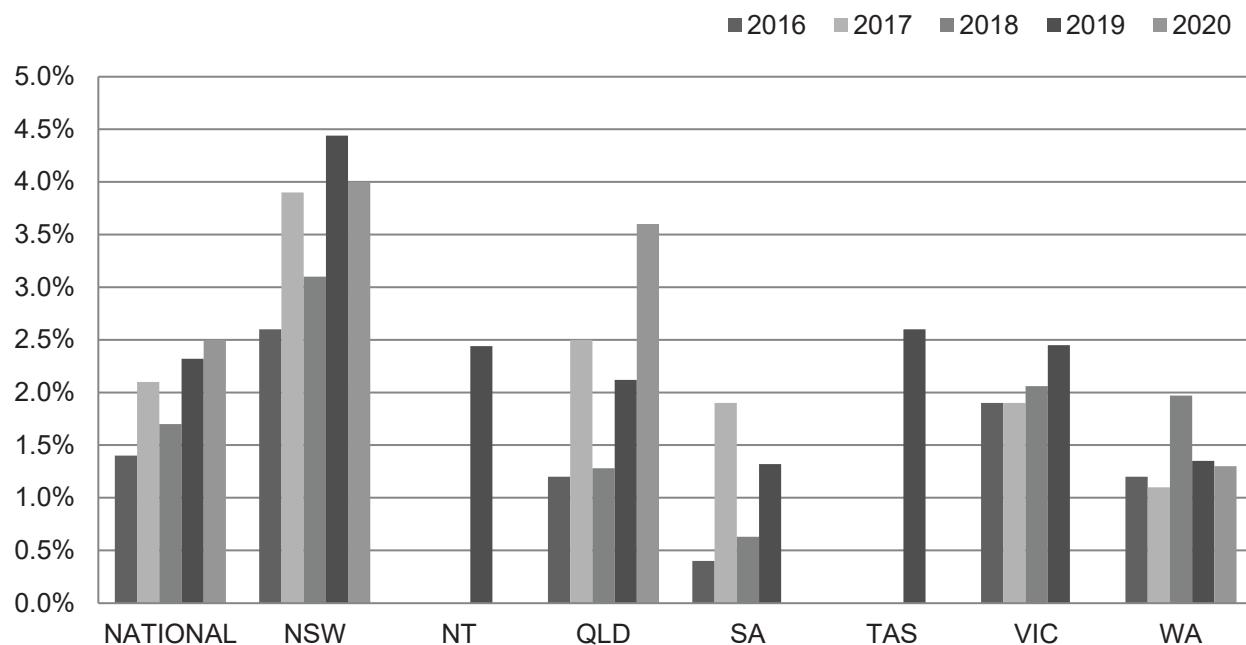

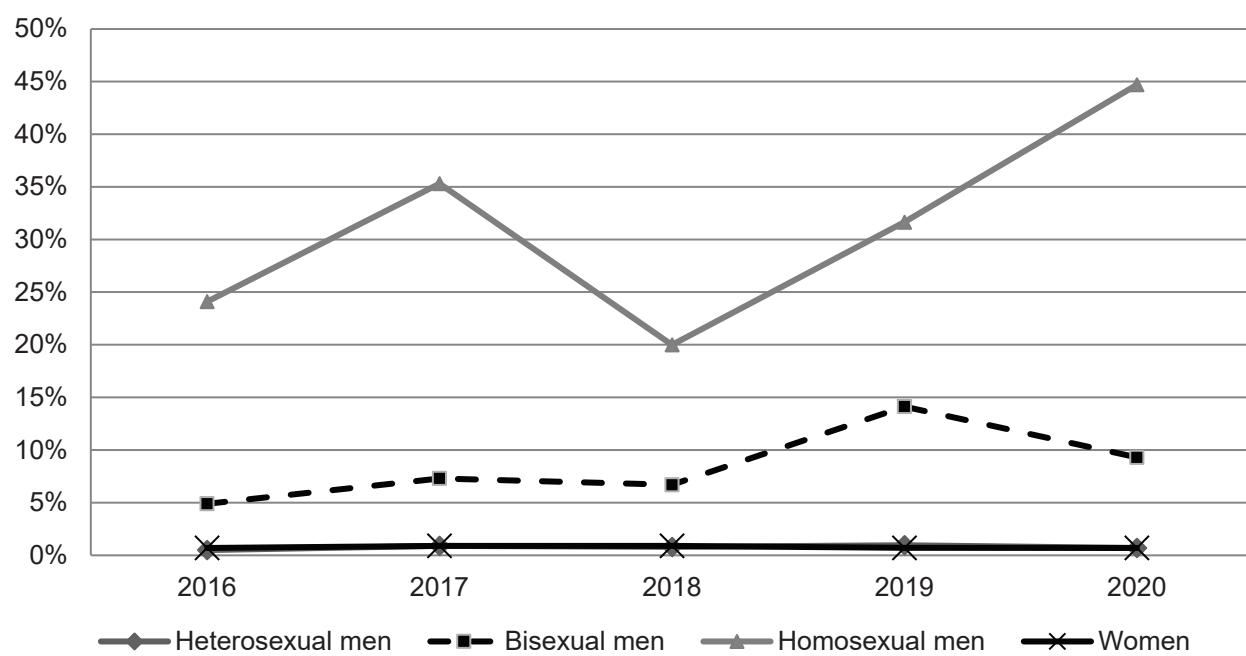

Respondents also reported high prevalence of lifetime HCV diagnostic screening over the period 2016 to 2020 (range 80% to 83%). In 2020, almost half (48%) of respondents reported an HCV diagnostic test in the previous 12 months, however a significant decline in recent (last 12 months) HCV diagnostic testing was observed over the period 2016 to 2020 (χ^2 trend $p=0.002$).

HIV antibody prevalence

HIV antibody prevalence remained low nationally over the period 2016 to 2020 (range 1.4% to 2.5%), however a significant increase was observed over this 5-year period (χ^2 trend $p=0.029$, Table 1.2.1). The increase in HIV antibody prevalence was also observed when data from Victoria were excluded (χ^2 trend $p=0.030$).

HIV prevalence was low and stable in all jurisdictions (Figure 4). No respondents in the Australian Capital Territory, and no women in South Australia or Tasmania tested positive to HIV antibodies in any of the previous five years, 2016 to 2020.

Nationally, HIV antibody prevalence was consistently higher among homosexual male respondents than among bisexual and heterosexual male or female respondents in all years, (Table 1.2.2 and Figure 5)⁵. HIV prevalence was also higher among men who reported methamphetamine as the last drug injected (5.4% in 2020) compared to men who reported last injecting all other drugs (1.2% in 2020, Table 1.2.4). In 2020, HIV prevalence was significantly higher among men who reported sex work in the month preceding the survey compared to men who did not report recent sex work (15.4% vs 2.9% respectively, $p=0.008$, Table 1.2.10).

Figure 4. HIV antibody prevalence (%) by jurisdiction, 2016–2020**Figure 5. HIV antibody prevalence (%) by gender and sexual identity, 2016–2020**

In all years 2016 to 2019, respondents from an Aboriginal and/or Torres Strait Islander background were significantly more likely to test HIV antibody positive than non-Indigenous respondents ($p<0.05$). However, no significant difference in HIV prevalence was observed between Indigenous and non-Indigenous respondents in 2020. In addition, prevalence of HIV infection among Aboriginal and Torres Strait Islander respondents remained stable between 2016 and 2020 (range 2.8% to 3.6%, χ^2 trend $p=0.886$). Of the eight Indigenous respondents who tested HIV antibody positive in 2020, half ($n=4$) identified as heterosexual.

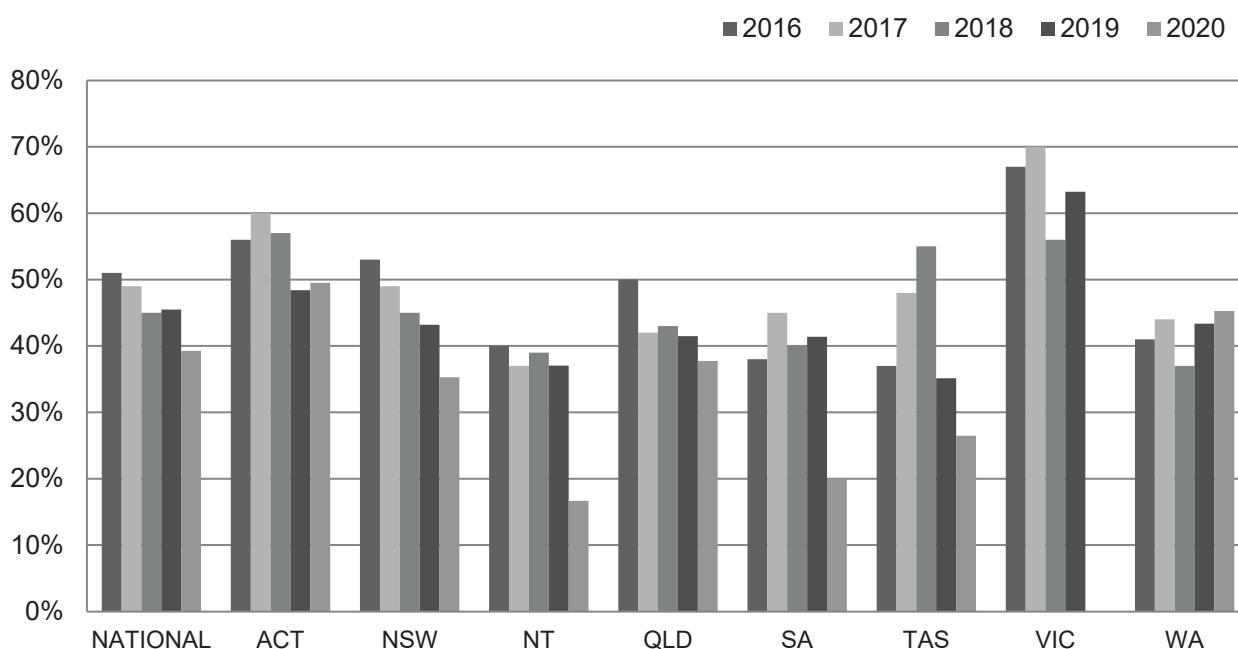

In 2020, the median age of respondents living with HIV was 50 years (range 24 to 64 years) and the median time since first injection was 16.5 years (range 2 to 46 years). In 2020, and comparable to previous years, 75% of respondents living with HIV reported they were on antiretroviral treatment.

HCV antibody prevalence

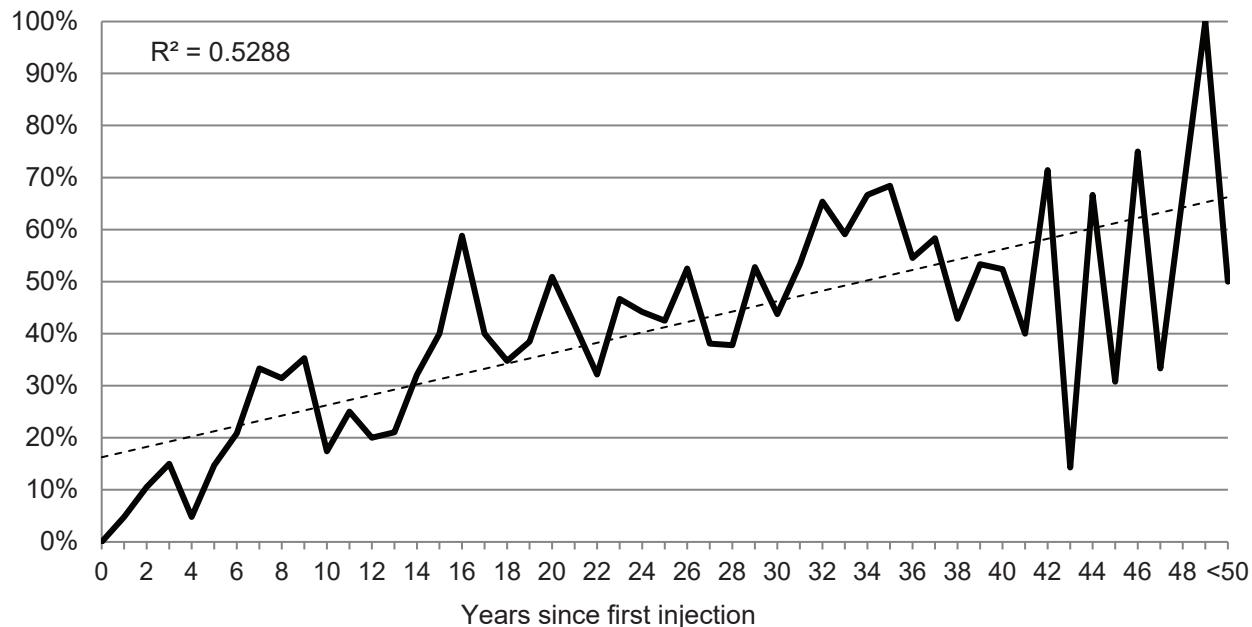

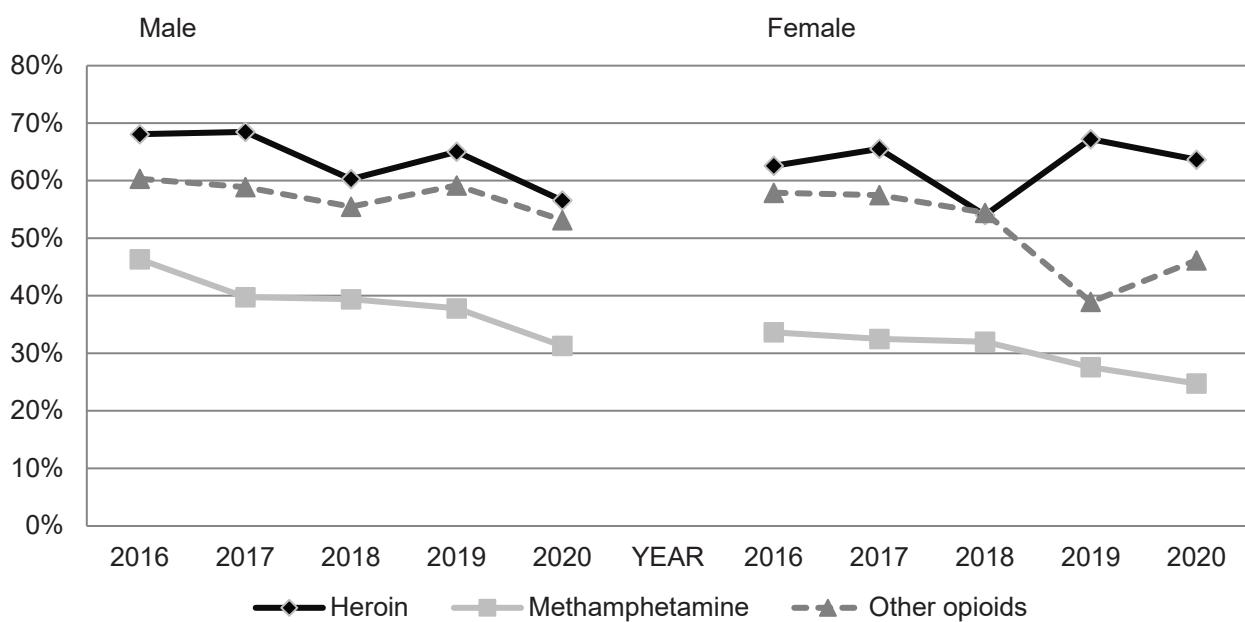

HCV antibody prevalence declined significantly nationally, from 51% in 2016 to 39% in 2020 (χ^2 trend $p<0.001$, Table 1.3.1), with a similar significant decline observed when data from Victoria were excluded (χ^2 trend $p<0.001$). Over the five-year period 2016 to 2020, HCV antibody prevalence declined among both men (from 52% in 2016 to 39% in 2020, χ^2 trend $p<0.001$) and women (from 47% in 2016 to 40% in 2020, χ^2 trend $p=0.006$).

At the jurisdictional level (Figure 6), declines in HCV antibody prevalence were observed in most jurisdictions. Across all five years of the survey, HCV antibody prevalence was significantly higher among older respondents and those with longer injection histories (Table 1.3.3 and 1.3.4). Figure 7 illustrates the relationship between exposure to HCV and time since first injection among respondents in 2020.

Figure 6. HCV antibody prevalence (%) by jurisdiction, 2016–2020

In all survey years, prevalence of HCV was also higher among respondents reporting heroin or other opioids as the last drug injected compared to respondents who last injected methamphetamine (Figure 8). HCV antibody prevalence was also consistently higher among respondents who reported imprisonment in the year preceding survey completion compared to those who did not ($p<0.010$ in all years 2016 to 2020) and among respondents who reported an Indigenous background ($p\leq0.001$ in all years 2017 to 2020).

Figure 7. HCV antibody prevalence (%) by time since first injection, 2020**Figure 8. HCV antibody prevalence (%) by drug last injected and gender, 2016–2020**

HCV RNA prevalence

HCV direct acting antiviral (DAA) therapies have been available through the Australian Government's Pharmaceutical Benefits Scheme (PBS) since March 2016. To determine HCV viraemic prevalence the ANSPS commenced HCV RNA testing in 2015. While 89% of the sample had sufficient DBS for HCV RNA in 2020, less than half of respondents were tested for HCV RNA in 2016. To adjust for potential sample bias in the RNA tested sub-sample, weightings were applied to HCV RNA data for all years (2016 to 2020) to adjust for gender (given higher rates of spontaneous clearance among women) and HCV antibody status. Results with small sample sizes, particularly at the jurisdictional level, should therefore be interpreted with caution.

As previously stated, HCV antibody prevalence declined significantly (from 51% in 2016 to 39% in 2020, χ^2 trend $p<0.001$) and lifetime HCV treatment increased significantly (from 29% in 2016 to 62% in 2020, χ^2 trend $p<0.001$). Among respondents who were tested for HCV RNA and after applying weightings, the proportion with detectable HCV RNA (active infection) also declined significantly, from 33% in 2016 to 16% in 2020 (χ^2 trend $p<0.001$). As shown in Figure 9, HCV RNA prevalence declined significantly among both males (37% in 2016 to 17% in 2020, χ^2 trend $p<0.001$) and females (26% in 2016 to 15% in 2020, χ^2 trend $p<0.001$).

Figure 9. Proportion of respondents (%) with detectable HCV RNA* by gender and survey year

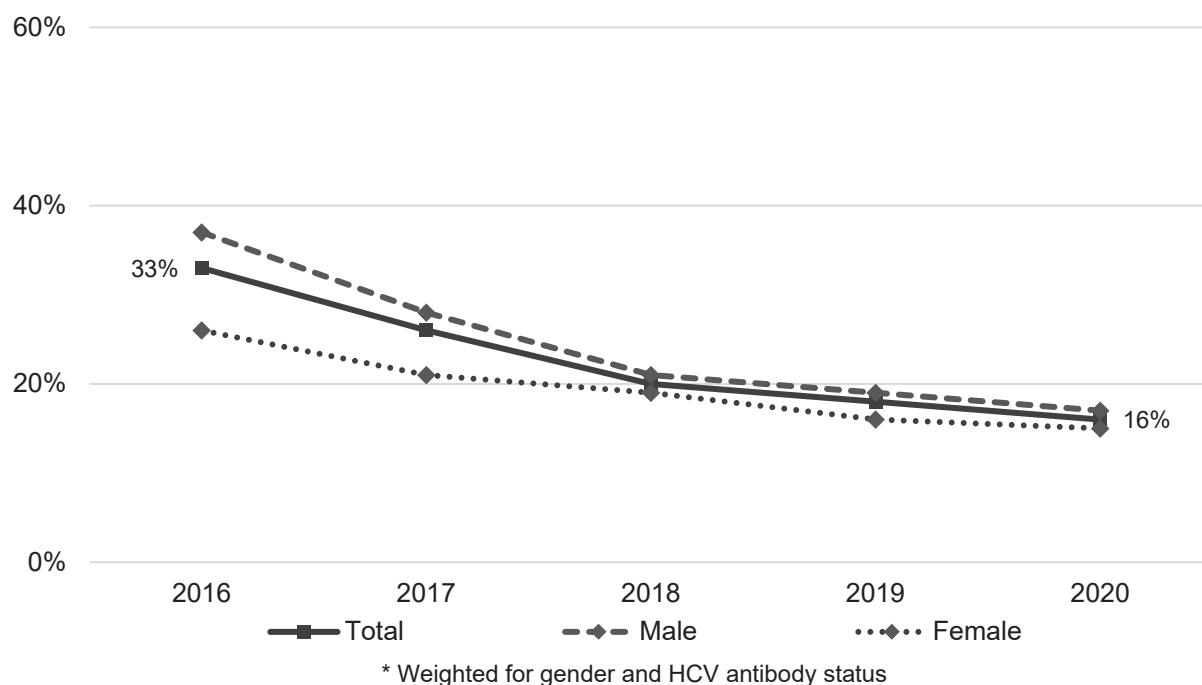

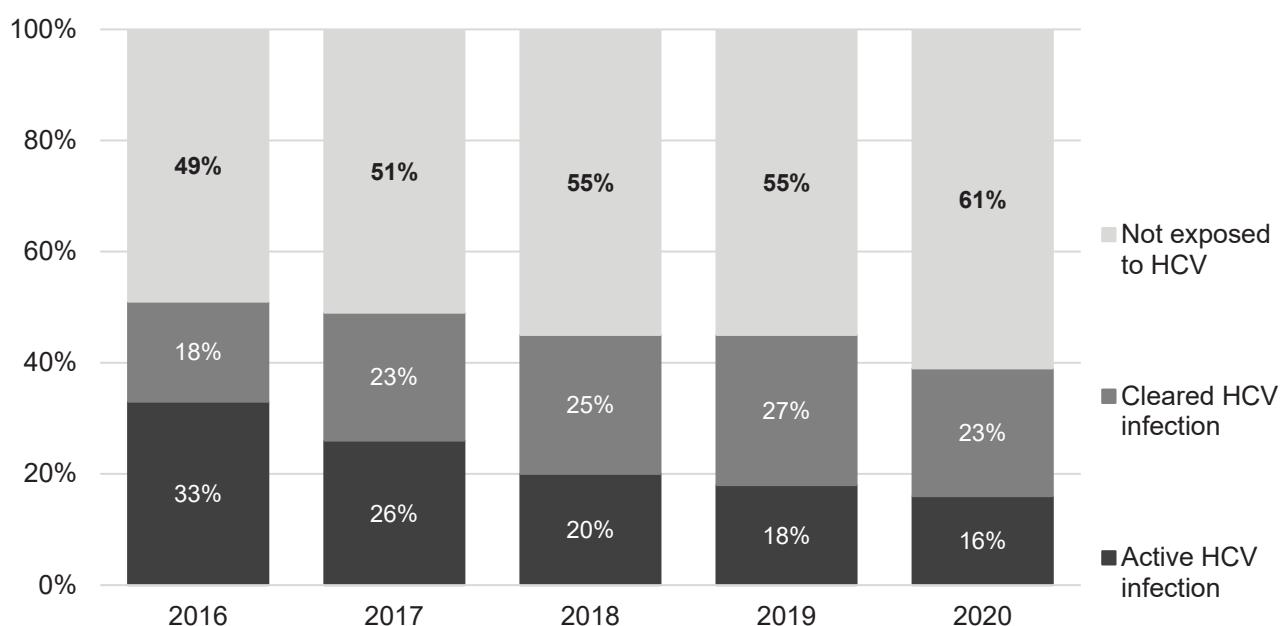

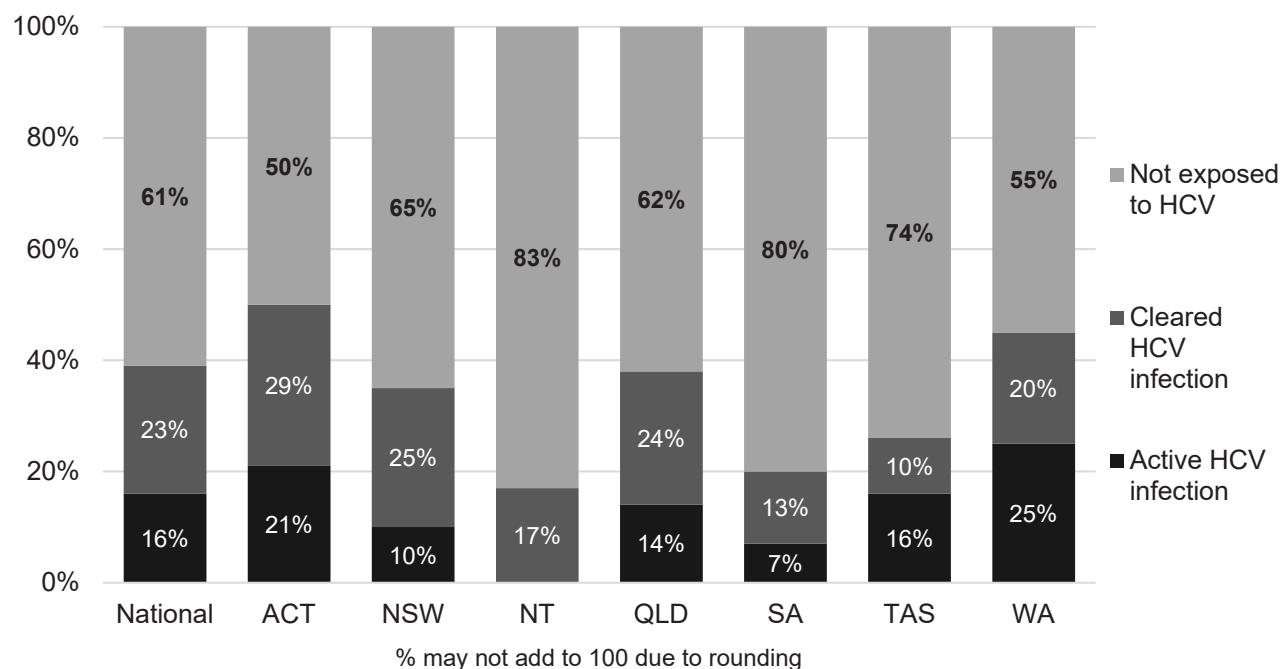

Figure 10. HCV viraemic status (%) by survey year

Results of HCV antibody and RNA testing can be combined to provide an estimate of viraemic prevalence among respondents⁶. As shown in Figure 10, the proportion of respondents with no evidence of exposure to HCV (HCV antibody negative) increased from 49% in 2016 to 61% in 2020 and the proportion with cleared infection (HCV antibody positive and HCV RNA negative) increased from 18% in 2016 to 23% in 2020, resulting in a 52% decline in the proportion of respondents with active HCV infection over the five-year period, 2016 to 2020.

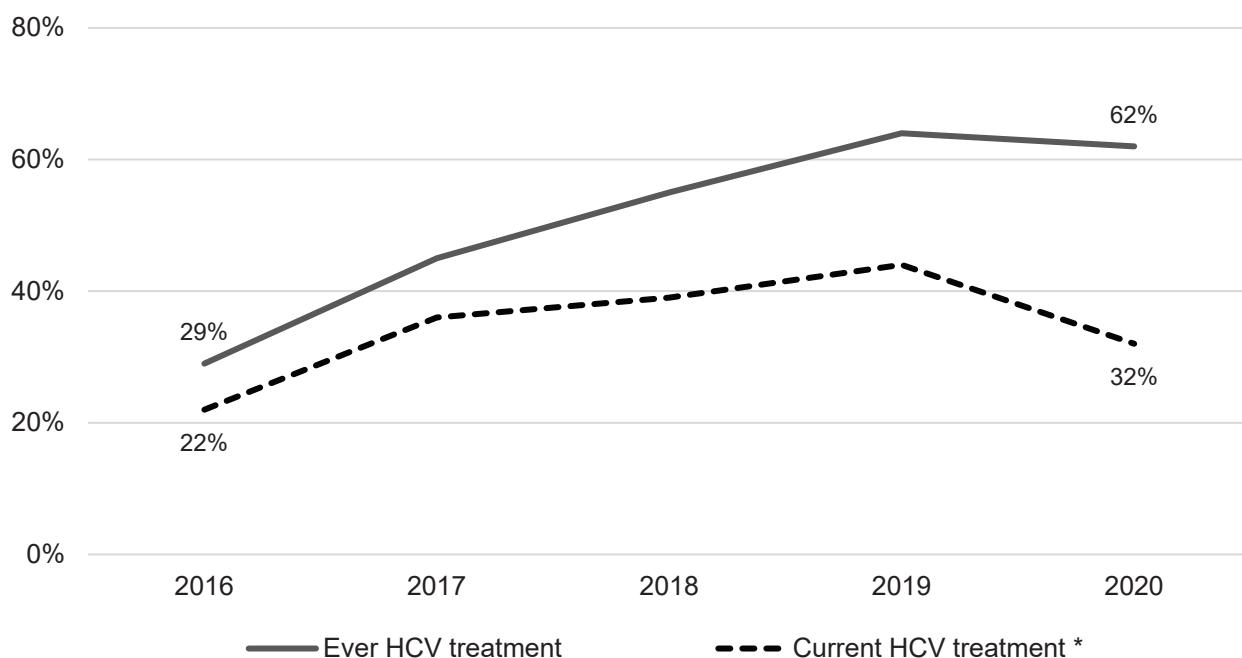

Figure 11. HCV viraemic status (%) nationally and by jurisdiction in 2020

HCV treatment

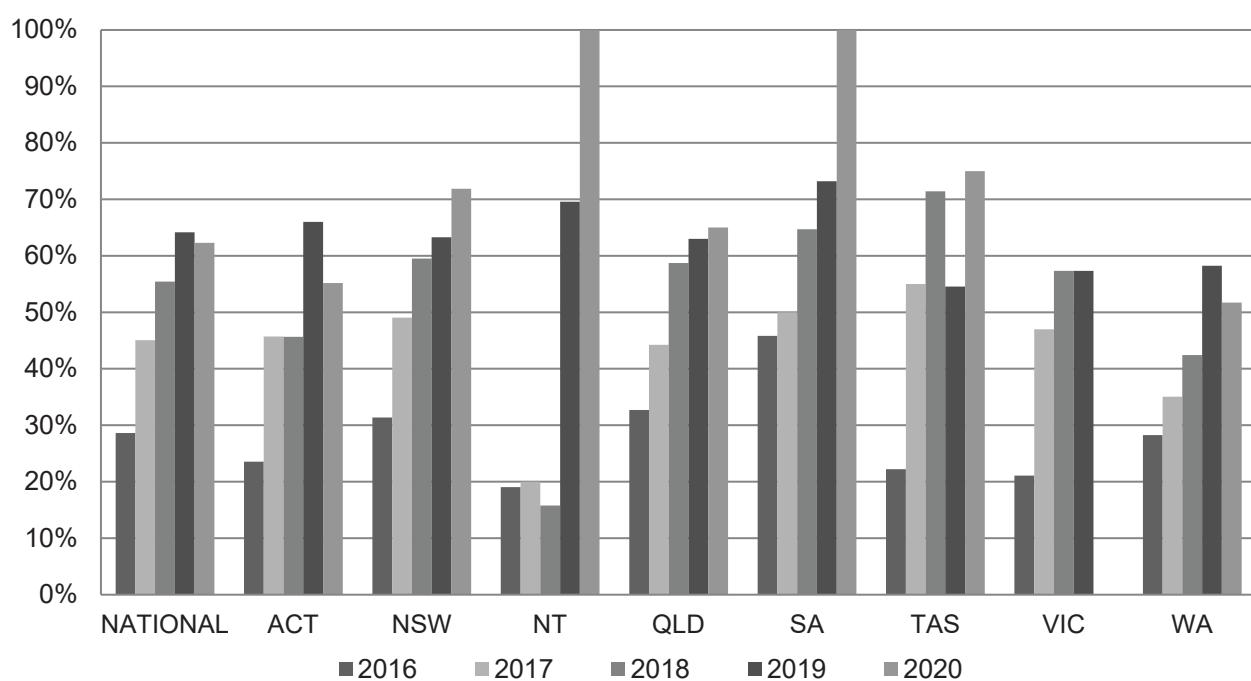

Among respondents who tested HCV antibody positive and after excluding those who reported spontaneous HCV clearance, the proportion who reported a lifetime history of HCV treatment increased significantly, from 29% in 2016 to 62% in 2020 (χ^2 trend $p<0.001$, Figure 12). Similarly, among respondents who tested HCV antibody positive and after excluding those who reported spontaneous or treatment-induced clearance more than 12 months previously, the proportion who reported recent (last 12 months) HCV treatment increased significantly, from 22% in 2016 to 32% in 2020, (χ^2 trend $p<0.001$, Figure 12). These trends were observed among both men and women. However, the increasing trend in lifetime HCV treatment uptake that occurred between 2016 and 2019⁶ was not maintained between 2019 (64%) and 2020 (62%, $p=0.628$) and there was a significant decline in the proportion of people who reported recent HCV treatment between 2019 (44%) and 2020 (32%, $p=0.002$). The decline in recent HCV treatment uptake between 2019 and 2020 was observed among men (47% vs 31% respectively, $p=0.002$) but not among women (39% vs 32% respectively, $p=0.345$).

Figure 12. Proportion of respondents (%) reporting lifetime and recent* HCV treatment among HCV antibody positive respondents who did not report spontaneous clearance by survey year

* The denominator for recent HCV treatment excludes those who reported prior HCV treatment induced clearance.

Figure 13. Lifetime history of HCV treatment (%) nationally and by jurisdiction, 2016-2020

X ² p trend		<0.001		0.320		<0.001

* Weighted for gender and HCV antibody status

A number of NSW samples were subject to a failed run due to incompatability with the HCV RNA testing platform in 2016

Totals include respondents where gender was reported as other or not reported

Appendix B: Methodological notes

Capillary blood was obtained by finger-prick using disposable lancets and cotton-fibre blotting paper. Dried blood samples were kept at room temperature at the survey sites and couriered to a central laboratory every second or third day. HIV antibody was detected using the Murex 1.2.0 ELISA (Diasorin). Repeatedly reactive specimens were subjected to Western blot confirmatory testing (Bio-Rad New LAV blot 1, France). A modified third generation enzyme immunoassay (Monolisa anti-HCV Plus Version 3 EIA, Biorad, France) was used to test for HCV antibody. A modified cut off value for optical density was calculated to capture greater than 95% of the seronegative population. Specimens were considered positive for HCV antibody if the optical density to cut off ratio was greater than or equal to one on initial and subsequent testing.

Between 2016 and 2020, HCV RNA was detected and quantified on the Hologic Panther™ using the Aptima™ HCV Quant Dx assay (Hologic, Inc. San Diego, Calif) which has a limit of quantitation (LOQ) 10 IU/mL and an upper limit of quantitation of 10^8 IU/mL in plasma. An offboard DBS elution protocol was applied prior to sampling. To correct for haematocrit, all post run DBS VL results on the Aptima assay were multiplied by a plasma conversion factor of 36.36. This calculation was based on the following assumptions: 45% haematocrit average per DBS, 50uL DBS volume and 1000uL Aptima transport media volume. A qualitative result of <10IU/mL detected (trace-equivocal) was applied to samples <400IU/mL (plasma equivalency).

Data presented in this report were analysed using Stata, Version 14 (Stata Corporation, College Station TX). Temporal changes in HIV/HCV antibody and HCV RNA prevalence were assessed using the χ^2 test for linear trend. Associations between demographic and behavioural variables and HIV/HCV antibody and HCV RNA prevalence were assessed using the χ^2 test or Fisher's exact test where frequencies were less than five. It should be noted that a sub-sample of respondents had sufficient DBS sample for HCV RNA testing. While sample yield has increased over time (from 35% tested in 2016 to 89% tested in 2020), HCV RNA tables were weighted to account for sample bias with respect to HCV antibody status and gender. Weights were applied to national data and to each individual jurisdiction, such that jurisdictional HCV RNA results will not necessarily add to data presented at the national level. Results with small sample size, particularly at the jurisdictional level, should be interpreted with caution.

Percentage values in tables may not add to 100 due to rounding. Totals in HIV and HCV antibody prevalence tables stratified by gender include people whose gender was not reported or reported as other. Time since first injection was calculated by subtracting age at first injection from age at survey completion. Totals in HIV and HCV antibody prevalence tables stratified by time since first injection include people who did not report age at survey completion or age at first injection. Tables reporting HIV antibody prevalence stratified by demographic and drug use characteristics are not included in this report for states and territories or survey years where the number of HIV antibody positive participants was less than 5 in all years.

Where data were collected but no participants endorsed a particular response, results are presented as "0 (0)". The symbol "--" shown in some tables denotes missing data; and is used to identify circumstances where data were not collected in the reported format. The vast majority of survey questions were consistent over all survey years.

NSP staff recorded sex, age group and survey participation for all clients at the NSP during the survey period and this data was used to assess response rates. Some clients visited the site more than once during the survey week, and only one attendance per person was included in the response rate denominator. Ethical approvals for the study were obtained from Human Research Ethics Committees associated with the investigators and participating sites. Verbal rather than written informed consent was obtained to assure the anonymity of participants.

Appendix C: List of tables

1. Demographic characteristics and drug use

- Table 1.1.1 Number (percentage) of respondents by demographic characteristics and survey year
- Table 1.1.2 Number (percentage) of respondents by last drug injected, frequency of injecting and survey year
- Table 1.1.3 Number (percentage) of respondents by injecting behaviour in the last month and survey year
- Table 1.1.4 Number (percentage) of respondents by treatment for drug use and survey year
- Table 1.1.5 Number (percentage) of respondents by testing for HIV and HCV, HCV treatment by survey year
- Table 1.1.6 Number (percentage) of respondents by sexual behaviour in the month prior to survey and survey year
- Table 1.1.7 Number (percentage) of respondents by COVID-19 related behaviours in 2020

2. HIV antibody prevalence

- Table 1.2.1 HIV antibody prevalence by gender and survey year
- Table 1.2.2 HIV antibody prevalence by sexual identity, gender and survey year
- Table 1.2.3 HIV antibody prevalence by age group, gender and survey year
- Table 1.2.4 HIV antibody prevalence by last drug injected, gender and survey year
- Table 1.2.5 HIV antibody prevalence by years of injection, gender and survey year
- Table 1.2.6 HIV antibody prevalence by re-use of someone else's used needle and syringe last month, gender and survey year
- Table 1.2.7 HIV antibody prevalence by frequency of drug injection last month, gender and survey year
- Table 1.2.8 HIV antibody prevalence by imprisonment last year, gender and survey year
- Table 1.2.9 HIV antibody prevalence by condom use at last sex with regular partner, gender and survey year
- Table 1.2.10 HIV antibody prevalence by sex work last month, gender and survey year
- Table 1.2.11 HIV antibody prevalence by Aboriginal and Torres Strait Islander origin status, gender and survey year
- Table 1.2.12 HIV antibody prevalence by main language spoken at home by parents, gender and survey year
- Table 1.2.13 HIV antibody prevalence by region/country of birth, gender and survey year

3. HCV antibody prevalence

- Table 1.3.1 HCV antibody prevalence by gender and survey year
- Table 1.3.2 HCV antibody prevalence by sexual identity, gender and survey year
- Table 1.3.3 HCV antibody prevalence by age group, gender and survey year
- Table 1.3.4 HCV antibody prevalence by years since first injection, gender and survey year
- Table 1.3.5 HCV antibody prevalence by re-use of someone else's used needle and syringe last month, years since first injection and survey year
- Table 1.3.6 HCV antibody prevalence by last drug injected, years since first injection and survey year
- Table 1.3.7 HCV antibody prevalence by frequency of drug injection last month, years since first injection and survey year
- Table 1.3.8 HCV antibody prevalence by imprisonment last year, years since first injection and survey year
- Table 1.3.9 HCV antibody prevalence by Aboriginal and Torres Strait Islander origin status, gender and survey year
- Table 1.3.10 HCV antibody prevalence by main language spoken at home by parents, gender and survey year
- Table 1.3.11 HCV antibody prevalence by region/country of birth, gender and survey year

4. HCV RNA prevalence

- Table 1.4.1 HCV RNA prevalence by gender and survey year
- Table 1.4.2 HCV RNA prevalence by sexual identity, gender and survey year
- Table 1.4.3 HCV RNA prevalence by age group, gender and survey year
- Table 1.4.4 HCV RNA prevalence by years since first injection, gender and survey year
- Table 1.4.5 HCV RNA prevalence by re-use of someone else's used needle and syringe last month, gender and survey year
- Table 1.4.6 HCV RNA prevalence by last drug injected, gender and survey year
- Table 1.4.7 HCV RNA prevalence by frequency of drug injection last month, gender and survey year
- Table 1.4.8 HCV RNA prevalence by imprisonment last year, gender and survey year
- Table 1.4.9 HCV RNA prevalence by Aboriginal and Torres Strait Islander origin status, gender and survey year
- Table 1.4.10 HCV RNA prevalence by main language spoken at home by parents, gender and survey year
- Table 1.4.11 HCV RNA prevalence by region/country of birth, gender and survey year
